## CHAPTER 1

### INTRODUCTION

Information used in this volume is given and discussed in detail in the other report volumes; most notably Volume 2, Agriculture and Social Studies; Volume 3, Groundwater; and Volume 4, Engineering. These describe the sources of data used. They include the results of formal surveys carried out as part of this study that covered 60 shallow tubewells (STWs) and hand dug wells, 16 private sector STW drilling contractors, and selected deep tubewells (DTW) mainly in the Bhairahwa Lumbini Groundwater Project (BLGWP).

A wide range of other data, from formal sources and informal discussions with His Majesty's Government of Nepal (HMGN), Agricultural Development Bank of Nepal (ADB) and other officials, as well as with farmers, are presented in the relevant report volumes. These other sources included the preliminary results of the 1991 Population Census and the 1990/91 National Sample Census of Agriculture available from the Central Bureau of Statistics (CBS).

This volume starts with some selected socio-economic background to the study area and an outline of the financial and economic analyses that have been carried out. Chapter 3 presents the derivation of financial prices and economic values used in the analyses. The following three chapters present the individual crop budgets for the different analysis strata and cases (Chapter 4) and the individual tubewell models and their benefits (Chapter 5, STW; Chapter 6, DTW) that form the basis for the analyses. Chapter 7 summarises the capital and operating costs that are given in detail in Volumes 3 and 4. Chapters 8 and 9 present the results of the financial and economic analyses for STWs (Chapter 8) and the larger, medium and deep tubewells (Chapter 9).

The viability of using tubewells in conjunction with surface irrigation is examined in Volume 1, Chapter 10.

The Study Area is shown on Figure 1.1.

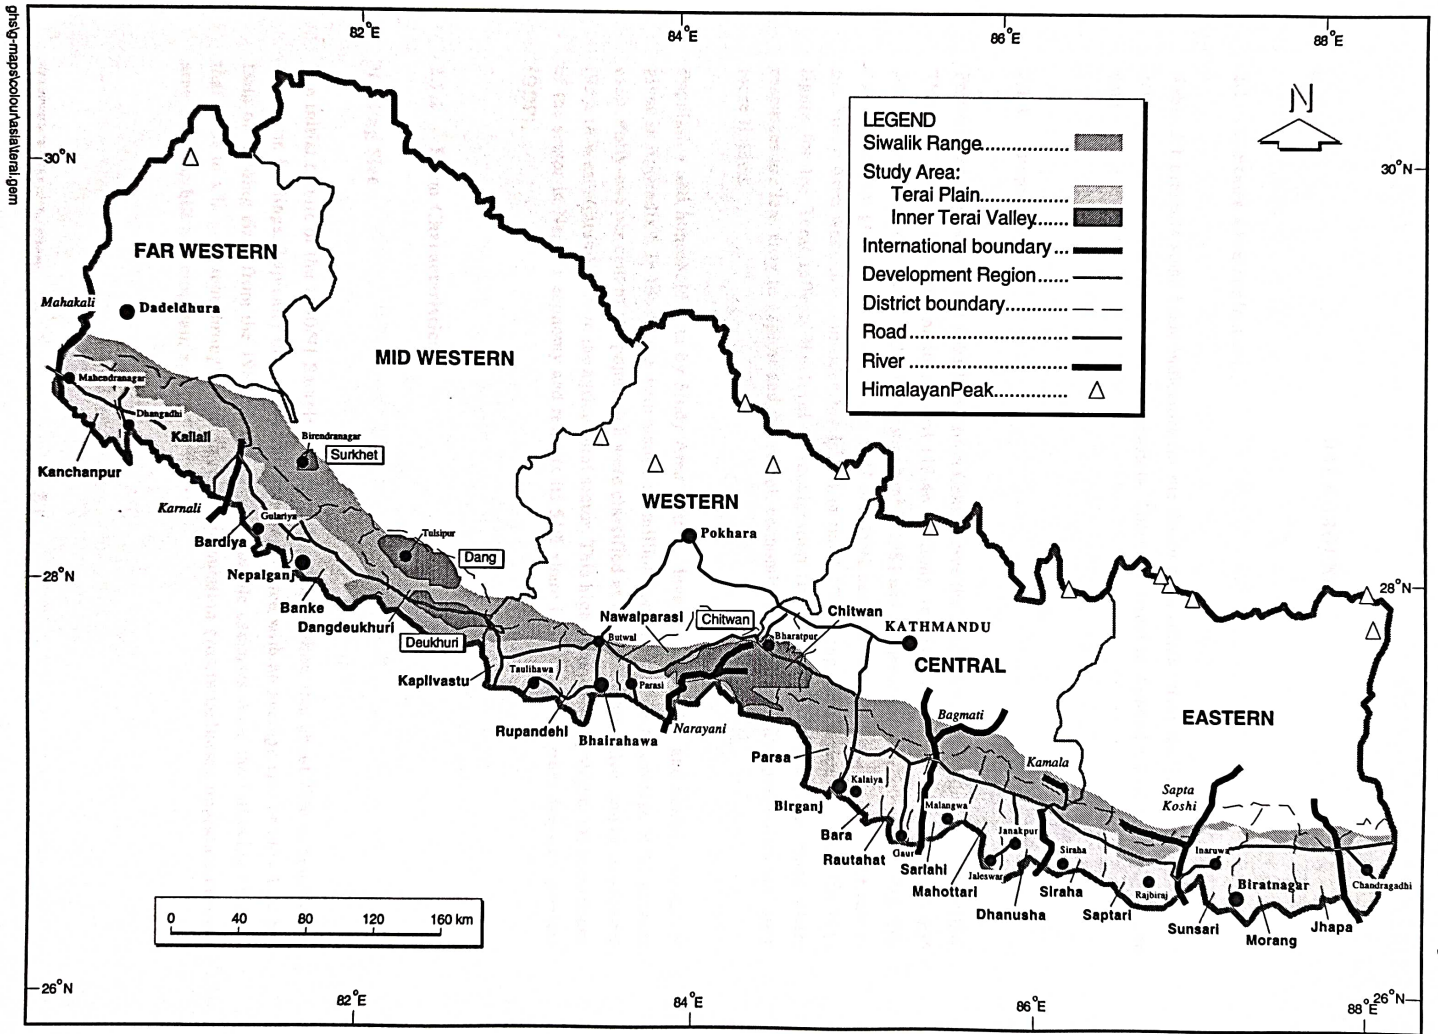

Figure 1.1  
Study Area

## CHAPTER 2

### BACKGROUND

#### 2.1 Study Area Indicators

Table 2.1 presents some basic indicators for the Study Area which cover the Terai and inner Terai ecological zones of 22 administrative districts. These are listed in Appendix I with the population data.

##### 2.1.1 Population

Preliminary results from the 1991 Population Census give the Study Area population at 9.05 million. This is almost half of the national total (18.46 million), representing an overall density of 235 persons/km<sup>2</sup>. This compares with 178 persons/km<sup>2</sup> in 1981 and 118 persons/km<sup>2</sup> recorded in 1971. The national annual growth rate between the 1981 and 1991 censuses was just under 2.1%. The rate in the Study Area was 2.8%, considerably less than the 4.3% during the previous decade. The high figure for the Terai reflects the level of immigration from the hill and mountain zones where resources are less easy to exploit and the social, economic and educational opportunities are much more limited.

Population and household data by Study Area district, development region and analysis strata are given in Appendix I. In 1991 there were almost 1.6 million households with an average of 5.7 persons each. Forty-one per cent of the population were classified as economically active, and of these, 84% (95% in West stratum) were in the agricultural sector. This high proportion highlights the importance of the sector in Nepal's economy and reflects its 54% share in the national gross domestic product (GDP).

##### 2.1.2 Farm Characteristics

###### Holding Size

The initial results of the 1990/91 Sample Census of Agriculture show that about 70% of households have farm holdings. Typically these are small and fragmented with an average size of only 1.24 ha. Data on holding sizes from the 1980/81 and 1990/91 sample censuses show the following changes that arose to a large extent through the high rate of population growth including migration into the area from the hill and mountain zones.

TABLE 2.1

## Selected Study Area Characteristics

Item	Analysis Stratum			Main Terai	Inner Terai	Study Area
	West	Central	East			
<b>(a) Population 1991 *</b>

moderate suitability:						
for paddy	7	14	15	13	9	12
for other crops	32	23	13	22	32	24

Note: Populations are for the entire "Terai" districts and so include parts of the districts that are outside the Terai ecological zone.

Source: 1981 and 1991 Population Censuses, CBS;  
1990/91 Sample Census of Agriculture, CBS;  
LRMP Land System Report, 1988 Kenting Earth Science Ltd.

Holding size range (ha)	Holdings (%)		Area (%)		Area/holding (ha)	
	80/81	90/91	80/81	90/91	80/81	90/91
Marginal <1	58	58	9	19	0.24	0.41
Small 1-3	28	33	33	44	1.77	1.66
Medium 3-5	8	6	21	17	3.81	3.76
Large >5	6	3	37	19	9.94	8.41
All holdings					1.48	1.24

Apart from the marginal group (which surprisingly remains static), the figures, as expected with a rapidly rising population density, show a fall in average holding size, a decline in the number of larger holdings, and an increase in the number of small holdings. As illustrated in Table 2.1, farm holdings are smallest in the inner Terai (0.93 ha), and the largest in the West (1.44 ha).

Farm households in the Study Area averaged 6.3 persons each, and were larger than the average recorded for the nation (5.7 persons) in the 1991 Population Census. The number increased with holding size as illustrated below. Households were larger in the West than elsewhere: seven persons as compared to 6.1 to 6.3 persons.

Holding size range (ha)	Household size (pers)	10 - 64 years old	
		(Avg pers)	(%)
Marginal < 1	5.5	3.7	68
Small 1-3	7.0	4.9	70
Medium 3-5	8.9	6.2	69
Large > 5	10.0	7.1	71
All Holdings	6.3	4.3	69

About 70% of the people are in the economically active age group of 10 to 64 years of age. However, as shown in the individual crop budgets (Chapter 4), there seems to be a high propensity on many farms to hire labour under a variety of conditions, particularly in the medium and large categories, which include most of the present STW owners. More detail on holding size is given in Appendix I (Table I.4).

### Fragmentation

A key factor in the utilisation of tubewells is the difficulty experienced in laying out distribution systems in circumstances where landholdings are commonly fragmented.

The 1990/91 Sample Census data on fragmentation are given in detail in Appendix I (Table I.5). As shown below, the average number of fragments or parcels for each holding was 3.8. This varied from 2.7 fragments on marginal farms (under 1 ha) to 8.6 fragments on large farms over 5 ha.

Holding size range (ha)	Fragmentation on each holding	
	Average (Nr)	percentage with only 1 parcel
Marginal < 1	2.7	32
Small 1-3	5.0	10
Medium 3-5	7.2	4
Large >5	8.6	8
<b>All holdings</b>	<b>3.8</b>	<b>22</b>

Significantly, almost one-third of marginal holdings had only one parcel of land. Because of the small size of such holdings, average 0.41 ha, individuals need to be part of a group to even acquire STWs. Nevertheless, having land in one parcel does reduce complications when laying out irrigation distribution systems.

Table 2.2 shows the differences among the four Study Area strata. As might be expected, fragmentation of holding is greater in the areas where population density is highest, in the Central and East strata.

**TABLE 2.2**

**Fragmentation in the Terai All Strata**

Stratum	Number parcels (Nr)					Avg Nr parcels per HH	Population density (pers/km <sup>2</sup> )
	1	2-3	4-5	6-9	Over 10		
West	29	48	15	6	2	2.7	136

Source: 1990/91 National Sample Census of Agriculture (preliminary)

## Land Tenure

Data on land tenure is considered to be unreliable for a variety of reasons (See Volume 2C, Social Studies). The 1990/91 Sample Census of Agriculture preliminary results indicate that about 78% of holdings are owner operated, 19% owner-cum-tenant operated, and only 3% are tenant farmers. The latter is almost certainly a substantial underestimate arising from fears of any possible tightening of the various land reform measures taken in the past. The reported differences among the Study Area strata are:

Land tenure type	(Percentage)				
	West	Central	East	Inner Terai	Study Area
Operated owned	87	77	70	86	78
Owner-cum-tenant	11	22	22	12	19
Tenant only	2	1	8	2	3

(see Appendix I, Table I.6)

Tenancies may be for a fixed rent in cash or in kind or alternatively under share cropping arrangements (Volume 2C, Social Studies). The different forms of tenancy were found to be in the following proportions:

Forms of tenancy	Owner-cum-tenant (%)	Tenant only (%)
Fixed rent	24	33
Share crop	45	54
Other	31	13

The "other" category includes mortgage tenancies and other arrangements.

The data, though perhaps unreliable, do indicate the minimum extent to which share cropping and renting have to be taken into account in the final formulation of tubewell irrigation schemes. These will need to be flexible enough in terms of water and land use arrangements, that is water buying and selling and voluntary consolidation of plots or holdings, to enable farmers with different types of tenure to participate in this form of irrigation.

### 2.1.3 Irrigation Potential

The LRMP report at a reconnaissance level identified 16 720 km<sup>2</sup> as potentially irrigable. This is equivalent to 68% of the total cultivable area (23 720 km<sup>2</sup>). Of this amount, 64% was considered to be of high potential, 12% moderate and suitable for paddy and 24% moderate but not suitable for paddy. Variations in these proportions in the four Study Area strata are shown in Table 2.1.

## 2.2 Stratification

To simplify the analyses and at the same time reflect major differences within the Study Area, four strata were identified:

Stratum	Development Region(s)
Main Terai	
- West	Far and Mid West
- Central	West and Central
- East	East
Inner Terai	Mid West, West and Central

The characteristics of each stratum are described in Volume 2B, Agriculture in terms of land resources and other physical conditions.

The stratification takes into account the main East-West variation in climate, in particular the nature of the monsoon rains. These start earlier and last longer in the east and decline in both aspects as one moves westwards. This together with the degree of development, especially of physical infrastructure gives rise to differences in cropping patterns, yields, settlement densities, etc.

The 1986 LRMP study data for the main Terai identified the following broad differences in cropping:

Predominant pattern	Study Area Stratum		
	West (%)	Central (%)	East (%)
Paddy based	57	84	73
Maize based	39	7	7
Other	4	9	20

Included in the other patterns in the East and Central strata, respectively, are those incorporating jute and sugar cane.

The stratification in broad terms also provides useful reflection of cost differences within the Study Area, especially in terms of transportation of inputs and outputs (Chapter 3).

## **2.3 Scope of the Study Analyses**

### **2.3.1 Scope**

The study analyses centre on the four strata described above and three types of tubewell: shallow (STW), medium (MTW) and deep (DTW). The characteristics of the four strata are described in Volume 2B, Agriculture, Chapter 4. The costs and their variants are described in Volume 3, Groundwater. There are two parts to the analyses. The first uses the tubewell as the unit, and the second illustrates the economic returns to a proposed tubewell development project based on existing HMGN Agricultural Service Centres. The proposed approach is described in Chapter 5 of Volume 2B, Agriculture, and in Volume 1, Chapter 12.

Two analysis levels have been applied to tubewells: full benefit/cost and least cost or partial analyses.

The scope of the benefit/cost analyses and the characteristics of the shallow and medium/deep tubewells adopted for them are summarised in Table 2.3. More detail is provided in Chapters 8 and 9.

A number of least cost comparisons have been made between tubewell types, power sources, distribution systems, etc., and these are set out in Table 2.4. They were carried out for a 13 l/s STW and a 60 l/s DTW sited in the Central Stratum. Also, MTWs and DTWs of varying capacity were also compared. Further detail is given in Chapter 7.

### **2.3.2 Benefit Cases**

Three cases reflecting tubewell cropping performance were examined for STWs and two cases for larger tubewells. These are in addition to the without tubewell (without project) case that illustrates the returns from areas under rainfed conditions equivalent to individual tubewell commands. This is used to arrive at the incremental benefits of groundwater irrigation. The cases are as follows:

TABLE 2.3

**Source:** GDC

## **Base Case**

The base case is applied to all three well types and illustrates the level of benefits already achieved when tubewells are installed. It takes into account the existing low level of support services, current availability of inputs and market conditions. The case can be considered to closely reflect the minimum well utilisation rates and crop production levels that can be achieved.

## **Improved Performance Case**

The agricultural performance of tubewells, particularly STWs, has not fulfilled expectations. There are two main areas of underachievement: the area irrigated from the individual well, and the yield of crops grown.

The extent of these aspects is discussed in Chapters 4, 5 and 6, and in detail in Volume 2B, Agriculture, and 2C, Social Studies. Volume 2C, Social Studies, also assesses the improvements that can be reasonably anticipated if farmers are exposed to new ideas and given the necessary support.

The improved performance case can be considered the future with project position. It is adopted as such in the prefeasibility level project economic analysis. As discussed later, however, achievement does require a determined and effective effort to upgrade and target HMGN extension and research services and the support available from the Agricultural Development Bank of Nepal (ADBN) and the Agricultural Inputs Corporation (AIC) to farmers. The private sector can be expected to service groundwater irrigation but will also need encouragement and support from government and its related agencies, particularly in terms of credit and training. The proposed intensive programme described in Volume 1, Chapter 12 has been designed to achieve this.

## **STW High Utilisation Case**

If water selling and buying and group ownership can be successfully established, then the average area irrigated by 15 l/s STWs could increase very significantly from about 2.5 ha to 4 to 6 ha. Ideas to encourage these two aspects of cooperation are put forward in Volume 2C, Social Studies.

### **2.3.3 Prices**

Analyses have been carried out at present (1993) financial prices and projected (2005) economic values, in constant 1993 terms. Prices used are given in Chapter 3. Where enough detail is available and differences are considered significant, different prices and values are applied to each of the four Study Area strata.

### 2.3.4 Repayment Capacity

A key issue in the development of groundwater for irrigation is the ability of farmers, at very minimum, to cover all operating and maintenance costs. In addition, capital costs have to be met. The extent to which this is likely is covered in the analyses for those using each tubewell type (Chapters 8 and 9).

### 2.3.5 Other Analyses

The other analyses shown in Table 2.3 compare different aspects of well and distribution system construction and tubewell operation on a least cost basis, mainly in terms of the cost of water at the well head or to the field. The well types to which the individual analyses are applied are shown in the table. The specific aspects covered relate to power sources, type of well, type of distribution system, size of tubewell (from 15 l/s to 90 l/s) and for use of suction or force mode pumps. The main benefit/cost analyses have only been applied to the types of tubewell and distribution systems considered most appropriate to the Study Area conditions.

## CHAPTER 3

### PRICE ASSUMPTIONS

#### 3.1 General

This chapter sets out the basis for the financial prices and economic values used in the study analyses. Financial prices are for early to mid-1993.

Economic values, wherever possible, are border parity values and are forecast for the year 2005 in terms of constant 1993 prices. They are derived from the World Bank's Price Prospects for Major Primary Commodities 1990-2005 published in May 1993 and from other sources which are noted where relevant. The World Bank's published prices have been adjusted to 1993 constant values by applying the Manufacturing Unit Value (MUV) index. This is commonly taken as an indicator of world market price inflation for primary commodities.

Table 3.1 summarises the recent past and forecast international market prices adopted for the Study. Where world prices were not available or were inappropriate, the values are based on internal Nepalese, 1993 prices. These include, in respect of production inputs, labour, agro-chemicals (excluding fertilisers), transportation and services, including those represented by marketing margins.

#### 3.2 Exchange Rates

Mid-1993 currency exchange rates have been used:

Rs 49	=	US Dollar 1.00
Rs 160	=	Indian Rupee 100
Rs 73	=	Pound Sterling 1.00

#### 3.3 Economic Conversion Factors

##### 3.3.1 Standard Conversion Factor

A Standard Conversion Factor (SCF) of 0.9 has been adopted to convert financial prices to economic values. It allows for:

- the slight undervaluation of foreign exchange at official exchange rates; and
- the general level of taxes and duties relating to imported and exported goods; transfer costs within the national economy.

TABLE 3.1

Source: Price Prospects for Major Primary Commodities 1990-2005 World Bank, May 1993; Financial Times (London) and the Asian Wall Street Journal editions, June 1993.

The standard conversion factor (SCF) has been applied to internal marketing, handling and processing costs, including marketing margins.

### **3.3.2 Construction Conversion Factors**

Composite Construction Conversion Factors (CCF) have been calculated for the analyses. They are derived from three components of construction costs which have the following conversion factors (CF) applied to them:

(a) **Imported materials**

This includes all imported equipment and material, i.e., pumpsets, well casing, finished steel products, etc. Customs duties and sales tax are applied to these imports, and a range of CFs have been used to adjust for these in the economic analyses. If items are imported from India or SAARC countries, there is some reduction in customs duty. The net saving is not very great, however, and the deduction has not been made in arriving at the conversion factors. The factors applied to the broad construction cost components into which costs have been divided are shown in Appendix VI in which the composite conversion factors are calculated.

(b) **Local Materials**

Sales taxes are levied on local materials. The rates vary but are most commonly 10% and a CF of 0.9 has been adopted. This has been applied to construction materials of local origin (cement, stone, brick, etc.) and to steelwork that has been substantially finished or fabricated within Nepal.

(c) **Labour**

Skilled labour has been included at its financial cost, a CF of 1.00. A CF of 0.75 has been used to adjust financial costs to the shadow wage rate of unskilled construction labour (see Section 3.8.2). This is the same as applied to agricultural labour.

(d) **Transport**

Where transport is a significant and identifiable cost component, a CF of 0.72 has been applied. This is discussed further in Section 3.7.

### **3.4 Duties and Taxes**

As implied above, the values used in the economic analysis exclude customs duties and sales taxes that are levied on imports and local sales. They are included in the financial analyses.

### 3.5 Land Tax

Farmers are required to pay land tax to their local authorities. The tax is assessed at different rates depending upon the quality of the land. Four classes are defined separately for lowland and highland in the Terai and other regions. The definitions of the classes in the Terai are summarised in Table 3.2 and the rates levied in 1993/4 were:

Land class	Tax rate (Rs/ha)
Abbal	118
Doyum	107
Seem	89
Chahar	59

A high proportion of the areas expected to be selected for tubewell irrigation will fall into the Abbal and Doyum classes.

### 3.6 Updating Costs

Where necessary, costs have been updated using the national and Terai Zone Consumer Price Indices published by the Nepal Rastra Bank. The rates used are set out in Table 3.3.

### 3.7 Transport

Transport is a significant cost element in Nepal's economy, even in the flatter, more accessible Terai zone. Imports and exports (as well as internal Indian trade) all have to pass through India via Calcutta. While road conditions have improved during the past decade along the national east-west and north-south highways, internal access away from these is generally difficult. Farm to market roads are frequently poor, though travel is easier within the Study Area than elsewhere.

The East-West Highway or Mahendra Raj Marg and is paved and runs the length of the main Terai. There are a number of north-south links with the interior. The main ones are also paved, most notably the roads to Pokhara and Kathmandu. A series of north-south, mainly gravel, roads lead from the East-West Highway, providing access of variable quality within the Terai and penetrating into the hill zone in places. These roads also provide access for the marketing of inputs and exports to India.

**TABLE 3.2**

**Definition of Land Tax Classes in the Terai (1990)**

Land Class	Lowland Terai	Upland Terai
<b>Abbal</b>	<ul style="list-style-type: none"> <li>- good loam soil with no stones</li> <li>- suitable for paddy</li> <li>- capable of 200% annual cropping intensity</li> <li>- irrigated</li> </ul>	<ul style="list-style-type: none"> <li>- good loam soil</li> <li>- suitable for paddy, wheat, maize and other crops</li> </ul>
<b>Doyum</b>	<ul style="list-style-type: none"> <li>- good loam soil with no stones</li> <li>- suitable for 200% annual cropping intensity</li> <li>- irrigable in monsoon season only</li> </ul>	<ul style="list-style-type: none"> <li>- good loam soil with no stones</li> <li>- suitable for maize, millet, oil seed, etc.</li> </ul>

**TABLE 3.3**

**Consumer Price Indices 1988/89 to 1992/1993**

Consumer price indices	1988 1989	1989 1990	1990 1991	1991 1992	1992 1993(1)
<b>National</b>					
- overall index	161.3	179.9	197.6	239.2	249.8
- transport	150.6	181.7	183.3	235.9	247.8
- non-food items and services	153.7	177.2	193.4	223.1	238.4
<b>Terai</b>					
- overall index	159.6	175.0	192.1	233.5	241.9
- transport	151.8	181.8	184.5	na	na
- non-food items and services	154.3	179.0	193.4	na	na

Note: (1) to January 1993

Source: Nepal Rastra Bank (base year 1983/84 = 100)

There are no significant links by river, but two short railways cross from India, from Birganj to Raxaul (6 km into Nepal) and Bizalpura to Jayanagar (51 km). The former link is almost abandoned and the latter is the main access route to India.

There are five main customs posts spread along the border at Biratnagar (Morang), Birganj (Parsa), Bhairahwa (Rupandehi), Nepalganj (Banke) and Mechi (Jhapa).

The calculations of the economic values of inputs and outputs allow for transport costs across the Study Area at the following rates:

Stratum	Financial (rounded) (Rs/t)	Economic (rounded) (Rs/t)
East	805	580
Central	1 170	842
West/Inner Terai	1 580	1 138

The financial rates are based on updated prices from the National Transport Corporation. The economic CF of 0.72 is that calculated in some detail for the 1988 Transport Investment and Maintenance Strategy Study (TecEcon with Scott Wilson Kirkpatrick & Partners and East Consult

for HMGN and ADBN). Financial transport prices for fertiliser are a little different. As shown later in Table 3.6, costs provided by the Agricultural Inputs Corporation (AIC) include transport at the average cost met by the corporation. The economic values are based on the figures given above for each study stratum (Table 3.7 for fertiliser).

Local, farm to market, transport is by bullock cart or head load. Field studies in early 1993 found that while costs varied, they were typically Rs 1.8/100 kg for each kilometre. The farmgate cost and price derivations assume a 10 km distance resulting in Rs 180/t. Other transport costs, where applicable, such as those borne by merchants in moving goods from AIC depots to local markets, assume motor transport to which a CF of 0.72 is applied to convert to the economic cost.

### **3.8 Labour**

#### **3.8.1 Skilled Labour**

Skilled labour has been included in the financial analyses at its early 1993 cost. The shadow price of skilled private sector employees, i.e. drillers, masons, etc., has been taken to be the same as their financial cost. The rates paid are considered to reflect the full opportunity cost of such workers.

The same applies to HMGN and ADBN technical and professional staff that are included in the pre-feasibility project analysis. However, these public sector employees at the higher levels pay tax and the financial price has been adjusted by 0.85 to allow for this in the economic analyses. This adjustment has been applied to all those earning above Rs 40 000 a year, which is a simplification since tax starts at a lower salary at 10% and gradually increases to 25%.

#### **3.8.2 Unskilled Labour**

Unskilled labour for construction and agricultural work has been included at the 1993 daily rates which are discussed below. In the financial analyses, farm family labour has not been costed, though it has been included in the economic calculations.

Details of the cost and use of unskilled non-agricultural labour for drilling and construction are given in Volumes 3 and 4. Hiring of casual, daily paid workers by farmers is widespread. Permanent labour is also employed under varying conditions, including the system of bonded labour common in the West stratum of the Study Area.

It is common in all areas to provide cash and one or two meals each day. Wages are also often paid in kind. The 1993 Study survey showed 35% paid in kind. At harvest time, payment in kind is often in the form of a share of the crop harvested. At other times, payment is commonly in locally standard quantities of grain, varying from 4 to 7 kg/day.

Data are insufficient to arrive at definitive figures to distinguish between areas where wages are high and low. But they do vary among areas and for work in the peak (land preparation, paddy transplanting and harvesting) and off-peak (weeding, post-harvest) demand periods. Peak rates appear to be highest in the Central stratum and parts of the East stratum including Butwal and Bhairahwa and lowest in the West stratum where bonded labour is most common.

### Financial Wage Rates

The financial analyses include the cost of hired labour at the average Study Area rate found during field studies in early 1993. The results of the limited survey of 61 tubewells are summarised in Table 3.4.

TABLE 3.4

#### Daily Paid Wage Rates 1993

Type of wage	Average value		Combined average
	(%)	(Rs/day)	(Rs/day)
Paid in cash only	40	34	} 38
Cash and food	25	44	
Kind only	11	23	} 31
Kind and food	24	34	
Total	100	-	35

Source: GDC field studies 1993

Most farmers (65%) paid in cash, or with cash and meals at an average cost of Rs 38/day. Payment in kind, with and without meals, was reported by 35% of respondents. Assuming an overall farmgate paddy price of Rs 4.8/kg (see Section 3.10) the average value paid in kind was Rs 31 a day. In both cases snacks and meals were valued respectively at Rs 5 and Rs 15 a day. The overall weighted cost was Rs 35/day.

For a number of reasons this figure may be rather on the high side. It does not take into account the possibly lower cost of bonded labour that is widely used in the West, and the proportion of those paying in kind appears to be low when compared to some other studies. Nevertheless, if the proportion was increased from 35% to 75%, the daily average cost would only fall to Rs 34/day, a very small difference. So taking into account the level of detail required of the study and the data limitations, the average rate of Rs 35/day has been adopted for all the study strata.

The main survey only considered average wage rates over the whole year. A separate study was carried out in the Butwal and Bhairahwa areas to determine the difference in peak and off-peak season payments. When demand was high, the reported rate was Rs 62/day which fell to Rs 37/day during the off-peak period. The difference of 68% was much larger than the 25% found in the 1987 GDC study and may not be typical of the whole area. It could reflect the greater demand for casual labour in the area where the data were collected. Nevertheless it is considered adequate for the following calculation of the economic conversion factor used to obtain the shadow price of labour for the economic analysis.

Using the Butwal - Bhairahwa data, the area's financial wage rate was calculated using the following assumptions:

- (a) 65% paid on cash basis, 35% paid in kind;
- (b) peak period four months, off-peak eight months;
- (c) cash rates: peak Rs 62/day, off-peak Rs 37/day; and
- (d) value in kind consisting paddy at Rs 4.8/kg, snack at Rs 5/day, and meals Rs 15/day, giving a total cost of Rs 31/day.

The resulting financial cost was Rs 41/day, which is higher than for the Study Area as a whole.

The same assumptions were used to calculate the economic value of labour, except that paddy was valued at Rs 5.9/kg, the projected average study value used in the economic analyses (see Section 3.11.2). In addition:

- the resulting peak rate of Rs 53/day is taken to be the opportunity cost of labour during this period; and
- the opportunity cost of off-peak labour is half the calculated rate of Rs 36/day, or Rs 18/day.

This reflects the greater difficulty in obtaining work at such times. Any lower rate would not have taken into account the fact that rice and wheat threshing and storage have their own labour demands during a part of the off-peak season, especially at present levels of mechanisation.

The overall shadow rate was Rs 30/day.

The factor to convert the financial cost to its economic value is therefore 0.75 ( $\text{Rs } 30 \div \text{Rs } 41$ ). This conversion factor, when applied to the financial daily rate used in the study analyses (Rs 35), gives the shadow rate of Rs 26.

### 3.9 Agricultural Inputs

#### 3.9.1 Seed

Almost all farmers plant seed from their previous crop or purchase locally from other farmers. Improved varieties are available from the Agricultural Inputs Corporation (AIC), and the use of high yield variety (HYV) paddy and particularly wheat is widespread, though often using seed purchased some years previously. Table 3.5 sets out the estimated price of such cereal seed.

The farmgate prices are based on AIC's 1992/93 procurement and other costs, official agents, commission and an element for transport from the dealer to the farm by bullock cart. Such seed is available from AIC depots and local Sajhas (government administered cooperatives).

**TABLE 3.5**

**Financial Farmgate Value of Crop Seed Available from the  
Agricultural Inputs Corporation 1992/93 (Rs/t)**

Item	Paddy	Wheat	Maize	Oil seed	Pulse
AIC procurement price plus direct expenditure	8 400	6 650	7 450	16 330	14 400
Losses (%)	(4.0)	(0.8)	(0.65)	(1.2)	(3.36)
(Rs)	336	53	48	198	484
Sub total	8 736	6 703	7 498	16 528	14 884
Promotion and administration costs (3%) plus contingencies (2%)	437	335	375	826	744
Total price at AIC depot	9 173	7 038	7 873	17 354	15 628
Dealer commission (10%)	917	704	787	1 735	1 563
Transport to farm	180	180	180	180	180
Farmgate price	10 270	7 922	8 840	19 269	17 371
Assumed price (Rs/kg)	10.3	7.9	8.8	19.3	17.4
Output value 1992/3	4.8	3.9	3.9	12.9	12.9
Ratio seed to output value at financial price	2.1	2.0	2.3	1.5	1.3

Source: GDC estimate based on 1993 AIC cost data

Table 3.5 also derives the cost of oil seed and pulses for planting if purchased through AIC. The ratio of seed cost in financial prices for farmers to output is shown at the bottom of the table. These have been applied to the economic farmgate output values to estimate seed prices in the economic analyses. For potato, the ratio assumed was 2.0.

### 3.9.2 Fertilisers

The financial farmgate prices of fertilisers are given in Table 3.6. The prices are based on 1993 AIC data.

**TABLE 3.6**

**Fertilisers: Present Financial Prices 1993 (Rs/t)**

Source: Agricultural Inputs Corporation, 1993

AIC is effectively still the sole importer of fertilisers, even though it is now legal for private concerns to do so. However, procedures are not yet clear enough to enable importers other than AIC to claim the subsidies that HMGN still provides through the Corporation. The extent of the subsidies is shown in Table 3.6. The subsidies are substantial, varying from 8% for DAP to 48% for urea. AIC depots in each district are wholesale outlets only. The final distribution is through cooperatives (*Sajhas*) and private dealers. There are 2 500 dealers in Nepal, of which 700 are cooperatives. Cooperatives now are reported to receive no preferential treatment except when supplies are very low, when they will be given priority at AIC depots.

Table 3.7 gives the derivation of the economic value of fertilisers. The world market prices are from the World Bank's forecasts of May 1993 (see Section 3.1), adjusted to constant 1993 prices. The breakdown of costs is based on AIC data. HMGN subsidies have been excluded and transport costs to each stratum have been included at the rates discussed in Section 3.7. The average 1993 economic values for the Study Area strata compare with the AIC based farmgate financial prices with and without the subsidies as shown below:

	Rs/kg			
	Urea	Compound	DAP	KCB
<b>Financial</b>				
with subsidy	5.8	10.2	12.7	8.7
without subsidy	10.9	13.1	13.6	10.8
<b>Economic</b>	10.7	12.8	13.3	10.5

As shown in Table 3.7, the economic values are derived from AIC's early 1993 procurement prices valued CIF Calcutta.

### 3.9.3 Draught Power

Throughout the Study Area, farmers typically use bullocks for land preparation and transport. Daily hire rates including labour vary considerably from Rs 50 to Rs 80 with an average rate of about Rs 55/day which has been used in both the financial and the economic analyses.

Typical work rates quoted by farmers were 0.1 ha/day for ploughing and 0.27 ha/day for puddling.

### 3.9.4 Agro-chemicals

Herbicides are rarely, if ever, applied; but pesticide use, particularly on irrigated crops, has been increasing. Applications are typically still low and data for the Study Area on types and quantities applied are few. In the crop budgets, the cost of pesticides nevertheless has been included as values (costs) per hectare. The following are the financial costs applied to all four Study Area strata:

Crop	Cost of pesticides (Rs/ha)		
	Rainfed	Irrigated case	
		Base	Improved
Paddy	-	170	340
Wheat	-	70	140
Maize	-	80	160
Oil seed	-	-	70
Pulse	-	-	70
Potato	100	200	600

For maize, no application of agro-chemicals has been assumed for yields below 1 600 kg/ha. For yields of 1 600 to 2 000 kg/ha, Rs 80/ha has been assumed, for yields over 2 000 kg/ha, Rs 160/ha has been assumed. The economic value is derived using a standard conversion factor (SCF) of 0.9.

### 3.9.5 Containers

Most farmers use purchased containers only for that proportion of their crops that are marketed. Nevertheless, there are costs involved in home storage, and the crop budgets include an element for this. The cost is based on the use of sacks at Rs 24 each with a useful life of four years, resulting in an annual cost of Rs 6/80 kg sack.

The 80 kg sack will contain the following weight of each commodity:

Crop	Weight/sack
Paddy	80 kg
Wheat	60 kg
Maize	60 kg
Oilseed	70 kg
Pulses	60 kg
Potato	65 kg

The Rs 6/sack cost has been used in the financial budget and adjusted by the SCF to Rs 5.4/sack in the economic budget.

### 3.10 Financial Crop Prices

Farmgate financial prices for crops in each Study Area stratum have been derived from 1991/92 and 1992/93 wholesale market data published by the Ministry of Agriculture (MOA) Department of Agricultural Development. The basis is the average for the two years which offsets the unusually high prices in 1992/93 that resulted from poor cropping conditions caused by the unusually light and late monsoon rains throughout Nepal.

To determine farmgate prices, a set of factors was used. They were calculated from GDC's 1992/93 farmgate price information and the same year's MOA wholesale prices in the Central stratum of the Study Area. The factors were found to be:

Crop	Factor
Paddy	0.90
Wheat	0.76
Maize	0.86
Oil seed	0.81
Pulses	0.76
Potato	0.58

The two years' wholesale prices and the adopted farmgate prices are given for each stratum in Table 3.8.

TABLE 3.8

### **3.11 Economic Crop Values**

#### **3.11.1 General**

The basis for calculating the economic values of the Study Area's major crops is described in Section 3.1.

The following sections and tables set out the derivation of the farmgate values of each crop in each of the four analysis strata. The currency exchange rates, transport costs, economic conversion factors, etc., have all been discussed above. The status of the major crops in the Study Area is described in Volume 2B, Agriculture.

#### **3.11.2 Cereals**

In the Study Area, three main cereals have been used in the analyses: rice, wheat and maize. Each of the crops is grown to provide first for the household's annual subsistence needs, after which surpluses are traded but the majority of farmers only sell small quantities. The Terai is a surplus cereal production area despite its fast growing population. However, redistribution to the deficit hill and mountain zones is hard and expensive. Terai surpluses, mainly of rice, are often directed to India. Over the past decade, Nepal's officially recorded figures show that the country is a net exporter of rice and at times of maize and an importer of wheat. However, exports have been erratic and falling.

Nepal has a rapidly growing population which may rise to 23 million by the year 2000 and 27 million by 2010, almost 47% higher than the 1991 preliminary population census figure of 18.5 million. This, coupled with the limited area available for crop expansion throughout the country, including the Terai, means that Nepal can expect to become a net importer of rice as well as other cereals in the foreseeable future unless yields are rapidly increased. The bulk of imports may be reduced since there is scope for considerable increase in cereal yields. However, this is from a rather low level and is highly dependent upon significant improvements in cultural practices as well as expansion in the area irrigated. This is unlikely to be sufficiently rapid to enable the production of consistent surpluses for export. Indeed in recent years, yields of cereals, oil seeds and pulses have either remained static or have declined. The three cereal crops have therefore been valued at their import parity prices.

The calculations to derive the economic farmgate value of cereals are shown in Table 3.9 for paddy, Table 3.10 for wheat and Table 3.11 for maize. The following comments supplement the information in the tables.

TABLE 3.9

## Rice

Rice is the predominant cereal traded in the Study Area. Sales on the main markets occur mainly from August to October, at or shortly after harvest. Lesser quantities may be available until March, reflecting the ability of larger scale farmers and petty traders to store and sell when prices increase. The majority of farmers, however, dispose of surpluses immediately after harvest.

Paddy is typically sold by farmers to petty traders or local storekeepers at the nearest village market. Larger scale merchants bulk up the crop from the initial buyers and move it to the main market centres to sell to wholesale merchants and millers who then sell the crop on the domestic or export market in India. Figure 3.1 illustrates this structure for paddy marketing.

Locally grown, dried and processed rice is of low quality, usually 30% broken. The Food Marketing Corporation (FMC) standard for imports is 15% broken. The World Bank's commodity data are for Thai 5% broken quality with an adjustment factor of 0.7 applied as shown in Table 3.9. The calculation also provides for the cost of transport to the different Study Area strata. Local traders', wholesale merchants' and importing agencies' costs, losses and profit margins are included at 10% at each stage in the marketing channel. Typical financial milling costs are Rs 400/t, which has been adjusted by a 0.9 SCF to give an economic cost of Rs 360/t. A 62% milling% has been assumed.

## Wheat

The import parity value of wheat at the farmgate was derived as illustrated in Table 3.10. Wheat and wheat flour are regularly imported, and local production is sold on the domestic market, apart from variable and usually unrecorded quantities exported to India in response to the two countries' border area price differentials.

## Maize

Maize, much like rice, is exported, but in small and unpredictable quantities. Recent data on maize trade are very sparse, but it can be predicted that domestic demand will exceed supply and, as with rice, the crop's economic value will be derived in terms of it being an import substitute. Table 3.11 shows the derivation of the maize farmgate values used in the economic analyses.

The forecast for 2005 farmgate values for maize at 1993 constant prices of the three cereals used in the analyses are:

Crop (Rs/kg)	Stratum			
	West	Central	East	Inner Terai
Paddy	5.7	5.9	6.0	5.7
Wheat	8.0	8.3	8.6	8.0
Maize	6.7	7.0	7.3	6.7

### 3.11.3 Other Crops

As illustrated in Volume 2B, oil seeds, pulses and vegetables are widely grown in the Study Area and have been included in the study analyses.

Vegetables are grown in small quantities (mainly irrigated) and are represented by potatoes in the crop budgets. Oil seeds, mainly mustard; and pulses, mainly lentils and chickpeas; are widely grown but tend to be replaced by wheat and vegetables when irrigation is introduced.

All three types of crop are traded under free market conditions and prices can be expected to be close to their real value reflecting demand and supply on both sides of the Nepal-Indian border. In each case, therefore, their financial prices have been taken as their economic values. The prices adopted are:

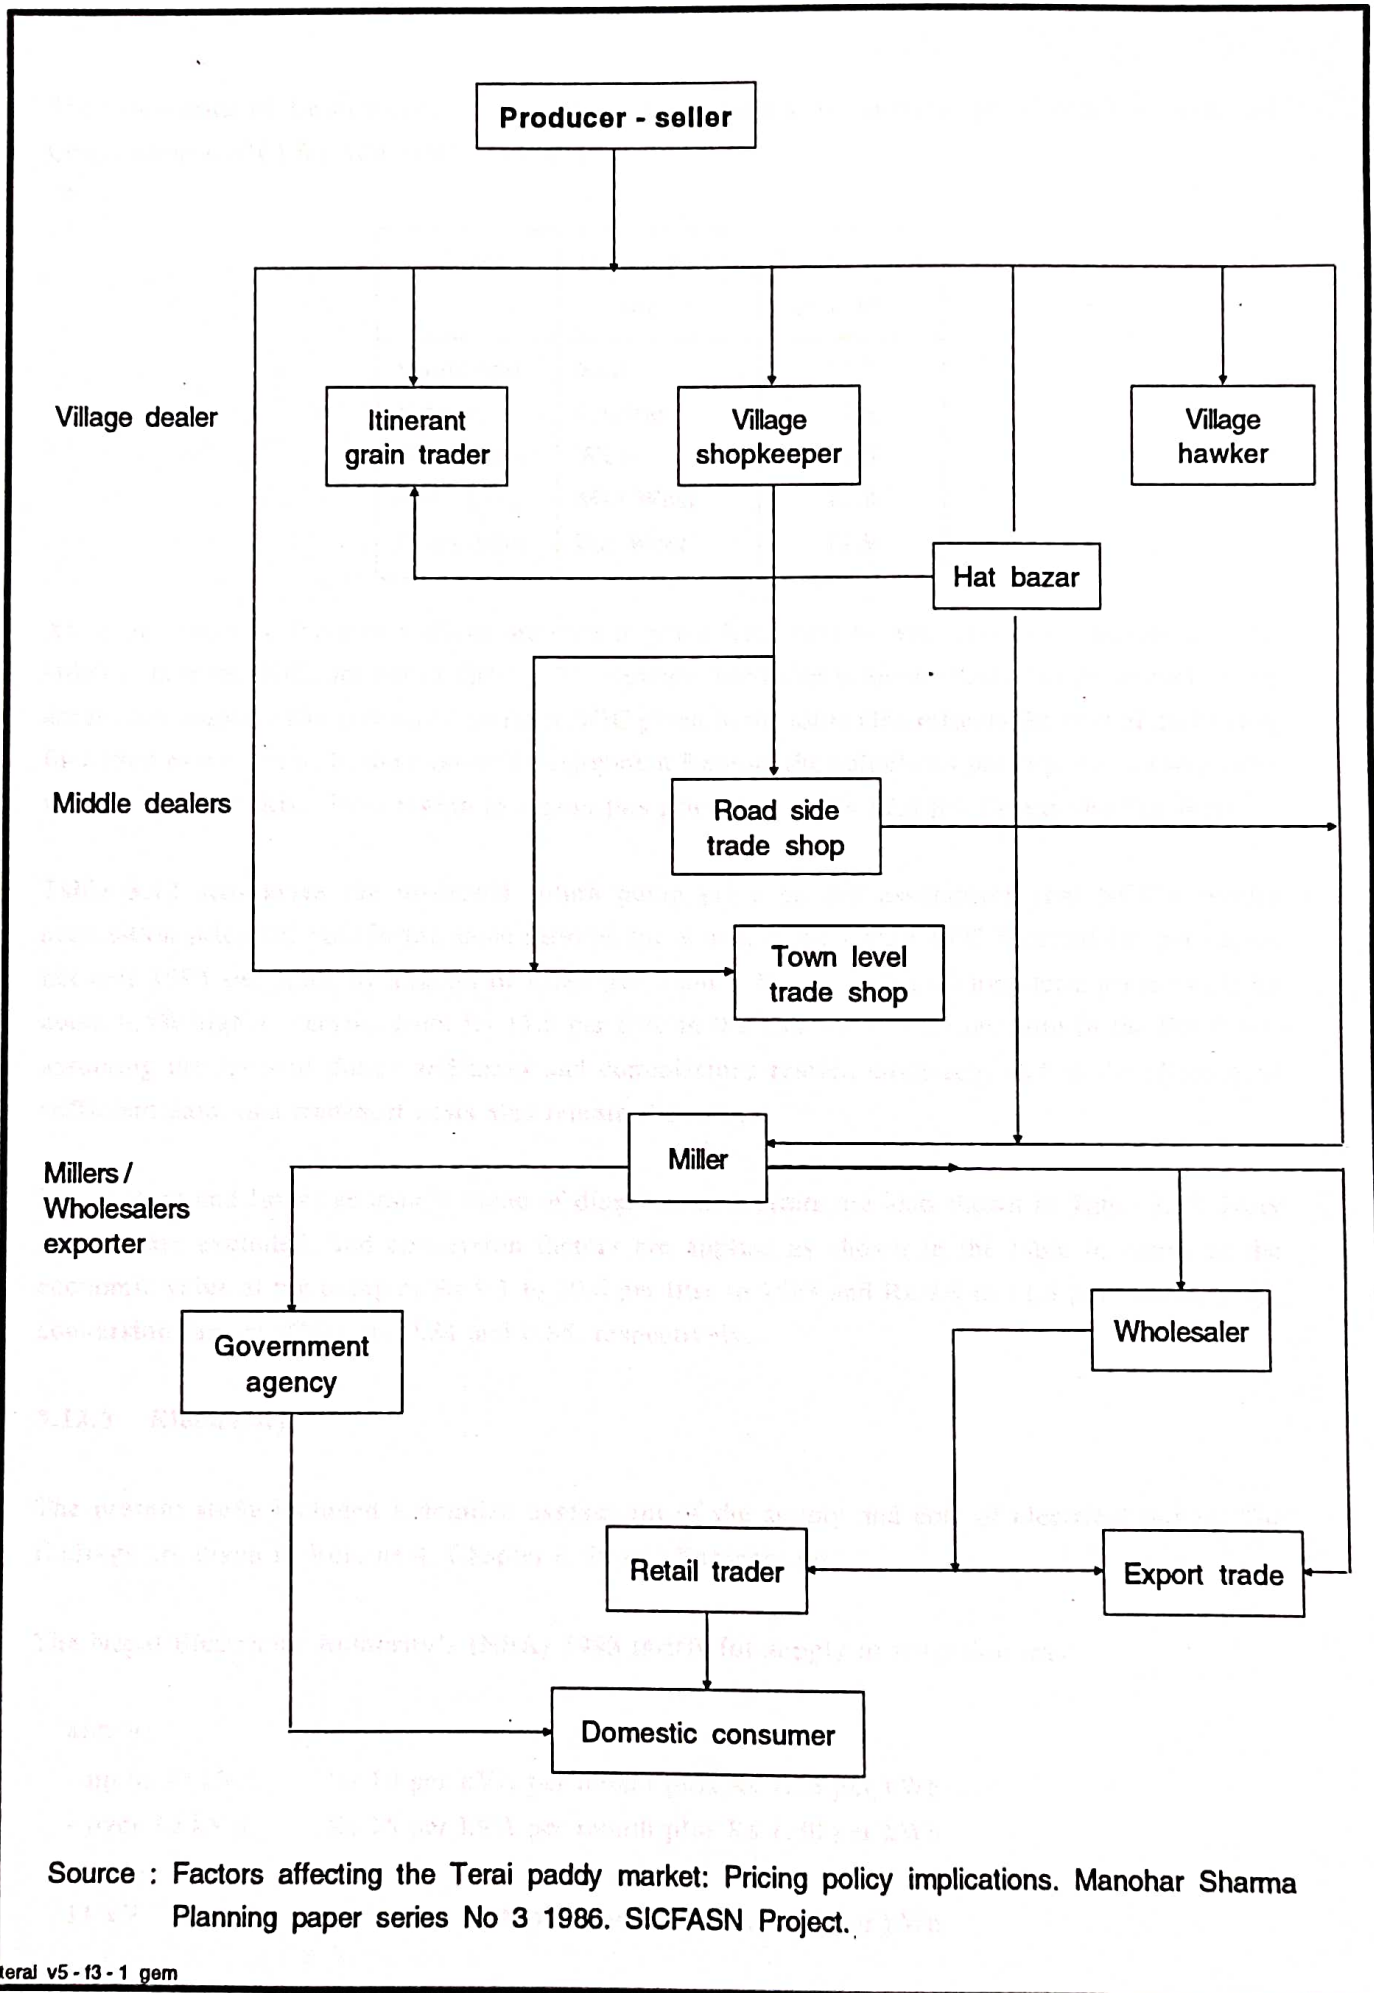

Crop (Rs/kg)	Stratum			
	West	Central	East	Inner Terai
Oil seeds	12.3	13.4	13.4	12.3
Pulses	14.8	14.0	13.2	9.5
Potatoes	2.7	2.5	2.4	2.7

## 3.12 Energy

### 3.12.1 Introduction

Two sources of energy for pumping to be considered are diesel and electricity (which is available in some areas). They are compared at long term projected prices, expressed in constant 1993 values that exclude inflation.

Marketing Channels for Paddy in the Terai

Source : Factors affecting the Terai paddy market: Pricing policy implications. Manohar Sharma  
 Planning paper series No 3 1986. SICFASN Project.

### 3.12.2 Diesel

The pump price of diesel varies throughout the Study Area as the figures below from the Nepal Oil Corporation (NOC) for mid-1993 illustrate:

Town	Development region	Retail price (Rs/litre)
Biratnagar	East	11.3
Birganj	Central	11.3
Bhairahwa	West	11.5
Nepalganj	Mid West	11.8
Dhangadhi	Far West	11.9

As to be expected, there is a slight increase in price from east to west reflecting transport costs. Other data from NOC, set out in Table 3.12, indicate that there is an element of cross-subsidisation across the country. The cost build up from NOC given in the table also reflects the cost of delivering fuel from east to west. In the Eastern Development Region, the calculated pump price in early 1993 was Rs 10.9 per litre. From region to region this price rose to Rs 12.5 per litre in the Far West.

Table 3.12 also gives the projected future pump price on the assumption that NOC's border acquisition price changes in the same ratio as the World Bank's May 1993 forecast for petroleum between 1993 and 2005; by a factor of 1.080 (ref Table 3.1). The expected long term price would be about 6.5% higher, varying from Rs 11.6 per litre in the East to Rs 13.3 per litre in the Far West, assuming the level of duties and taxes and commissions remain unaltered, and in the absence of sufficient data, that transport costs also remain the same.

The present and future economic value of diesel in each strata are also shown in Table 3.12. Duty and tax are excluded, and conversion factors are applied as shown in the table to arrive at the economic value at the pump of Rs 9.1 to 10.6 per litre in 1993 and Rs 9.8 to 11.4 per litre in 2005; conversion factors (CFs) are 0.84 and 0.85, respectively.

### 3.12.3 Electricity

The present study included a detailed assessment of the supply and cost of electrical power. The findings are given in Volume 4, Chapter 6, Power Engineering.

The Nepal Electricity Authority's (NEA) 1993 tariffs for supply to irrigation was:

400 V:

- up to 10 kVA, Rs 10 per kVA per month plus Rs 1.15 per kWh
- over 10 kVA, Rs 15 per kVA per month plus Rs 1.50 per kWh

11 kV Rs 20 per kVA per month plus Rs 1.40 per kWh

TABLE 3.12

Source: derived from Nepal Oil Corporation data

Only pumps operating less than 50 hours per month will pay enough through the demand charge to cover the cost of supply. While this may be applicable in some STW operations, the tariff contains a subsidy for most DTWs and some STWs.

The NEA has only outline plans for expansion to meet additional demand during the period before their major additional generation capacity Arun III, is installed in 2002 or 2003. In these circumstances, the NEA has not been able to provide any long range marginal cost (LRMC) for electrical power.

From the present until when Arun III is operational in 1992, the Electricity Sub-sector Management Assistance Programme of the World Bank (ESMAP) proposed the installation of 25 MW gas turbine generators as a stop-gap measure. Their figures for the LRMC of energy at the various supply voltages were Rs 3 430/MWh at 33 kV, Rs 4 263/MWh at 11 kV, and Rs 5 880/MWh at 400 V. The Rs 5 880/MWh for 400 V supply includes a substantial allowance for the so-called non-technical losses, (a euphemism for theft), and should be substantially reduced. It is not the fault of the paying customers that the NEA is unable to collect the revenue due on all the electricity delivered.

For economic analysis, the figure of Rs 4 263/MWh, Rs 4.263/kWh, is recommended since all DTWs will be connected directly to a transformer for the exclusive use of the well operation.

### **3.13 Summary of Financial Prices and Economic Values**

Table 3.13 lists the financial prices and corresponding economic values of crops and crop inputs adopted for the study analyses. The present 1993 financial prices and the future 2005 economic values are used in the analyses. The 1993 estimated economic values are included for comparison.

## CHAPTER 4

### CROP BUDGETS

#### 4.1 General

Four sets of crop gross margin budgets have been calculated. They illustrate the expected gross margins relevant to the three analysis cases described in Section 2.3.2. In each instance, the budgets have been prepared for the four Study Area strata to reflect differences found in yields and inputs described in Volume 2B, Agriculture, and the prices discussed in Chapter 3 of this volume. The sets of gross margins represent:

- present rainfed production;
- future rainfed production assuming that over a period of, say 12 to 15 years, HMGN and other support services do improve and enable changes in cultivation practices that raise yields to be adopted by the majority of farmers;
- existing practices and yields where year-round irrigation is available. This is equivalent to the base case referred to in Section 2.3.2. It is the minimum benefit from each crop that can be expected; and
- finally, the projected levels of production using groundwater when growers take up the range of better practices described in Volume 2, including good tubewell and in-field water management.

As implied above, it is clear that the agricultural performance of existing tubewells has not fulfilled expectations. There are two main areas of underachievement:

- the crop area irrigated from the individual STW (which is discussed in the next chapter); and
- the yield of crops grown under irrigation.

#### 4.2 Yields

The provision of water alone will immediately and without any other major inputs raise yields. This is the result of the farmers' ability to prepare land and transplant paddy at the most appropriate time, to harvest paddy and plant the following winter crop on time and to overcome any possible mid-season water deficits.

Yields of cereal crops have been shown to increase to the extent shown in Table 4.1 if given the provision of water but no other substantial outside advice or assistance.

**TABLE 4.1**

**Present Crop Yield Changes with Tubewell Irrigation (t/ha)**

Crop (t/ha)	Before TW	After TW	Increase %
Paddy	1.84	2.72	48
Wheat	1.12	1.70	52
Maize	1.19	1.42	19
Pulses	0.46	0.46	-
Oil seeds	0.50	0.56	12
Potato	5.27	10.12	92

Source: GDC 1993.

Paddy and wheat yields have increased about 50% and maize yields have increased almost 20% with the availability of year-round water. Oil seeds and pulses generally do not exhibit the same response to irrigation; although vegetables, including potatoes, will show very substantial increases of up to 100%.

The yield changes in Table 4.1 do not imply that farmers installing tubewells at present do not use more fertiliser or change cultivation practices. Rather, the changes they do institute are limited by their existing knowledge and unchanged circumstances. To realise more fully the potential of irrigation and increase yields further, farmers need to be exposed to new ideas: improved crop varieties, better cultivation methods including in-field water control and appropriate fertiliser applications, improved storage for surpluses, as well as access to recommended physical inputs, credit and markets.

If these conditions are met, yields of paddy and wheat, for example, can be expected to rise further to, say 3.5 to 4 t/ha and 2.5 to 3 t/ha, respectively. However, if this is to happen, additional investment and effort will be needed to make HMGN and other advisory and support services a great deal more accessible and effective. Such changes will take time to arrange, and under normal conditions there will be some delay before this second boost to yields can be expected to begin.

The requirements, both institutional and technical, for achieving such yields, as well as to improve tubewell performance in the respects discussed in Chapter 5, are detailed in Volume 2B, Agriculture.

During the development or project period used for the study analyses, there will be some improvement in rainfed (without project) crop yields. This will result from an expected gradual

improvement in HMGN and other support services and pressures on the farming community as population grows within the limited cultivable area in the Terai.

The yield assumptions adopted for the analyses are summarised in Table 4.2 for both the with and without project cases. Figure 4.1 illustrates diagrammatically the anticipated pattern of yield changes expected for a group of tubewells and farmers within tubewell command area.

The yield figures shown are those in Table 4.2 for paddy in the West stratum. In the figure:

- A-B is the immediate increase with irrigation and negligible changes in other conditions (1.70 t/ha to 2.80 t/ha);
- B-C is the period immediately following the installation;
  - B-C2 represents some yield improvement as the irrigator gains experience (2.80 to 2.95 t/ha);
  - B-C1 shows that without a project development there may be improvements in rainfed (- TW or minus project) crop yields brought about by the existing support services (1.70 to 1.80 t/ha);
- C-D once the recommended support services are organised, trained and put into operation (during B-C), further crop yield increases can be expected;
  - C-D2 from farmers' exposure to new ideas from the support services and easier access to inputs and markets from the service sector (2.95 to 4.00 t/ha); and
  - C-D1 during the same period, rainfed crop yields may also rise as a result of some general improvement in support services to the rainfed sector (1.80 to 2.15 t/ha).

In Figure 4.1, then, A-C1-D1 illustrates the without project (- TW) and A-C2-D2 the with project (+ TW) changes used in the analyses. The difference between D2 and D1, 1.85 t/ha paddy in the West stratum illustrated, represents the incremental yield benefit over a project period of, say 12 to 15 years. Full yields are given in Table 4.3.

**TABLE 4.2****Crop Yield Assumptions by Stratum (t/ha)**

Crop	West	Central	East	Inner Terai

future	13.00	13.00	13.00	13.00

Source: GDC estimates (Volume 2B, Agriculture)

**Figure 4.1**  
**Diagrammatic Illustration of Yield Benefit Build up with Irrigation**

- A - B = Increase with water only
- B - C = Slight increase as farmers gain experience
- C - D = Second phase increase resulting from improved extension advice and availability of required inputs

The improvements from A to C2 can be expected with an intensified development project. This is the period during which institutional improvements required to give better supporting and advisory services are put in place but before they become effective in the field.

Possible increase without irrigation (pre-tubewell yield = 1.70 t/ha)

**Note:** Indicative paddy yields taken for 'West' Stratum - see Volume 2, Part B, Tables 4.8, 4.9, 4.12 & 4.13.

There are other factors, of course, which will influence benefits to irrigation, particularly the annual cropping intensity and area irrigated from each well. These are discussed in the chapters on tubewell models.

### 4.3 Crop Inputs

The levels of crop inputs presently used and expected in the future under rainfed and irrigated conditions are discussed in Volume 2B, Agriculture. The inputs are summarised here and more information can be found in the Tables 4.3 to 4.10, presented as follows:

Crop Type	Table Nr	
	Present	Future
<b>Rainfed:</b>		
- Cereals	4.3	4.4
- Other crops	4.5	4.6
<b>With TW irrigation:</b>		
- Cereals	4.7	4.8
- Other crops	4.9	4.10

The inputs are appropriate to the yields noted in the previous section. A breakdown of the estimated labour inputs shown in the tables above is given in Appendix II.

### 4.4 Crop Budgets

Tables 4.11 and 4.12 summarise the financial and economic crop gross margin budgets adopted for the analyses.

The financial budgets included only the proportion of labour and the draught bullock work hired; the farmers' family's inputs are not included. The proportions of these two components that are hired are shown in the physical input tables in the previous section. These estimates are from the GDC 1987 field studies. The budgets at economic prices included all labour and bullock draught work.

The full budgets are set out in Appendix III.

## CHAPTER 5

### SHALLOW TUBEWELL BENEFITS

#### 5.1 STW Models

As outlined in Section 2.3.2 three STW models were examined:

- Base Case (BC) represents the present achievement by farmers with STWs. In this the area served by the model is low and cultural practices do not achieve the reasonable optimum levels that can be expected with reliable year-round irrigation water;
- Improved Performance Case (IPC) illustrating the future potential levels of production when growers have access to new ideas and necessary inputs; and
- High Utilisation Case (HUC) which assumes that 4 ha are irrigated from a STW. This implies that farmers have to group together to jointly own or sell and buy water from a STW in order to give irrigation access to something nearer a well's potential command area. It also assumes that individuals in such a STW users group cooperate closely in respect of water allocation and scheduling. The HUC is applied in the analyses to both the Base and Improved Performance Cases to illustrate the effect of larger command areas at present and in the future.

In addition, the benefits from the equivalent area of land as the tubewell model have been calculated to arrive at the incremental crop benefits for the analyses.

#### 5.2 Tubewell Coverage

Three tubewell surveys carried out since the early 1980s (APROSC 1983; GDC 1987; GDC 1993) illustrate the continuing low utilisation of STWs in terms of area covered. As shown in Table 5.1 all three surveys found command areas of less than 2.5 ha, and only 1.89 ha in the West and Mid West Regions in 1993. Table 5.1 does, however, indicate that there may have been an improvement in annual cropping intensities since the mid to late 1980s. With STWs, these have increased from 156% (1983) to 142% (1987) to a range (1993) between 168% in the inner Terai and 214% (in the East and Central strata) where spring paddy and/or maize were included in the observed cropping patterns. The latest study does therefore indicate some improvement in STW utilisation, but the low areas commanded (i.e., irrigated) from the great majority of wells remains poor.

**TABLE 5.1**

**Shallow Tubewell Performance 1983, 1987 and 1993**

Year	Average STW owners holdings (ha)	STW command area (ha)	Annual cropping intensities (%)	
			Before	After
1983	6.6	2.57	139	156
1987	6.9	2.45	127	142
1993				
West		1.89	143	197
Central		2.30	171	204
East		2.26	131	214
Inner Terai		2.54	90	168

**Note:** Intensities of over 200% indicate spring paddy

**Source:** APROSC 1983, GDC 1987, GDC 1993.

**Base Case**

Using the 1993 data in Table 5.1 as a guide, the STW models for the Base Case assume:

Stratum	Command area (ha)	Annual cropping intensity (%)
West	1.9	197
Central	2.3	204
East	2.3	214
Inner Terai	2.5	168

**Improved Performance Case**

In each stratum, the Improved Performance Case assumes the same command areas with an annual cropping intensity of 200% and, of course, the higher yields and inputs discussed in the previous section.

## High Utilisation Case

High Utilisation Case is also based on 200% annual intensity but with a larger, 4 ha command area.

It is apparent from the field studies and observations that the cropping intensities found include a proportion of land that does not receive irrigation in the winter season except when crops are under particular stress. This is common for oil seeds and pulses which typically continue to be grown using residual moisture conditions even when water is available. To simplify the crop models and to enable a direct comparison of with and without tubewell benefits, this factor has been allowed for in the oil seed and pulse crop gross margins shown earlier.

Table 5.2 sets out the annual cropping patterns that arise from these assumptions.

### 5.3 Incremental Benefits

The estimated incremental benefits are summarised in Table 5.3 at financial farmgate prices and in Table 5.4 at economic values. A detailed breakdown of the benefits with and without groundwater is given in Appendix IV.

### 5.4 Benefit Development

The analyses of STW under the different cases assume that farmers rapidly reach the Base Case cropping intensities shown in Table 5.2. The increase in cropping is fairly modest and the rate of build up assumed has been 60% for year one and 100 for year two.

More time will be required to achieve the High Utilisation and Improved Performance Cases. In both cases, the achievement will depend largely on the support services becoming a great deal more effective in conveying to farmers the benefits of group tubewell ownership or water buying and selling for the high intensity case and the improved cultural practices outlined in Section 4.2 for the improved performance case. Experience in Nepal has shown that neither of these occur automatically but will require a concerted effort by HMGN and others (refer to Volumes 2B and 2C). Therefore the STW analyses are confined to examining the effect of the wells under each of the conditions individually.

## CHAPTER 6

### MEDIUM AND DEEP TUBEWELL BENEFITS

#### 6.1 Tubewell Models

A number of medium (MTW) and deep (DTW) tubewell models have been evaluated. The different capacities and command areas of these are:

Item	Capacity (l/s)	Command area (ha)
DTW	90	90
	60	60
MTW with distribution system		
	- piped	
	- open channel	45
- open channel	45	36
- open channel	30	20

One set of cropping patterns that are related to land type has been adopted for MTW and DTW analysis. Table 6.1 sets out the cropping patterns for three types of land.

#### The Land System 2 (mixed)

This model will be the most common in any DTW programme. At the MTW and DTW command area scale of 30 to 90 ha there will be varying proportions, according to tubewell siting, of medium and upland areas within Land System 2. Table 6.1 shows that the proportions assumed for the study analyses are about 90% medium land and 10% upland, lowland areas would be avoided entirely. As described earlier, in Volume 2, upland areas are not suitable for paddy and have a maize/wheat based cropping pattern in contrast to paddy/wheat on medium land.

Two cropping patterns have been adopted to illustrate returns in Land System 2 (mixed) areas; one for the main Terai and another for the Inner Terai where cropping intensities are lower (refer to Volume 2C, Social Studies, Table 5.2). The patterns with and without tubewells are summarised in Table 6.1.

**TABLE 6.1**

**Cropping Patterns and Intensities: Deep and Medium Tubewells**

Crop	Land System 2 (mixed)				Class 2-Upland		Class 2R Lowland	
	w/o TW (%)	w/TW (%)	w/o TW (%)	w/TW (%)	w/o TW (%)	w/TW (%)	w/o TW (%) (1)	w/TW (%) (2)
Paddy	85	90	42	88	0	0	99	146
Wheat	20	65	8	61	0	50	0	0

- Notes: (1) spring paddy 18%  
 (2) spring paddy 46%

Source: GDC estimates

**Main Terai**

The without tubewell cropping pattern and annual intensity of 146% was derived from data in Table 5.2 for the four Study Area strata. When a tubewell is installed, the cropping intensity can be expected to rise to 195% and the proportion of paddy, wheat and vegetables will increase. Maize cropping will decrease in the winter, but because it is grown on upland areas its cropping pattern will remain unchanged in the monsoon season. Oil seed and pulse proportions are unlikely to change.

**Inner Terai**

With irrigation, the cropping intensity can be expected to increase significantly from the low 90%, rainfed levels observed during the present study, to 195% (refer to Table 5.2 and Volume 2B, Agriculture). As shown in Table 6.1, the major increase will be in paddy, wheat and vegetables. The proportion of maize in each season is unlikely to alter.

Two further cropping patterns have been examined for areas which are much less likely to be developed with MTWs and DTWs. Each has been applied to all four Study Area strata.

The Class 2 uplands only model is also given for areas where medium land is scarce.

The Class 2R lowland model is for areas which are poorly drained and suitable only for rice.

The systems are described in Volume 2A, Land Resources.

Table 6.2 gives the crop areas assumed for the MTW and DTW analyses based on the patterns in Table 6.1. Spring paddy is grown only on Class 2R land where drainage is very poor. While the crop is grown without irrigation, in the lower lying parts of such land, the availability of year-round water should enable farmers to increase the area under crop from under 20% to about 45% of the land available.

## 6.2 Incremental Benefits

The increase in benefits for the three land classes is summarised in Table 6.3.

The incremental benefits are given in terms of annual gross margins, each hectare at 1993 financial prices and forecast economic values (at constant 1993 prices). They apply to all five tubewell capacities. The figures are for the Central Stratum and have been calculated for the comparison of net benefits given later in this volume. The relative differences will be very similar for the other three strata. A full breakdown of the gross margins by crop showing the total gross margins for each tubewell is provided in Appendix V.

The incremental gross margins are calculated as follows:

**Present** the Base Case and Improved Performance Case, less the gross margin from the equivalent area of present rainfed cropping that they replace; and

**Future** the Improved Performance Case, less the projected rainfed production levels that were discussed in Chapter 4, Crop Budgets.

## 6.3 Benefit Development

As with STWs, the build up of benefits has been separately assessed for the Base and the Improved Performance Cases.

 FIP = future improved performance.

Source: GDC estimates

**Base Case**

The need for a large group of farmers to work together in MTWs and DTWs is expected to result in a rather slower build up of benefits compared to the two years (60% and 100%) for STWs (Section 5.4). A four year build up is assumed at the following rate:

Year	1	2	3	4
Percentage of full incremental benefit	40	70	90	100

This takes into account both the increase in yields and cropping intensities, the latter are likely to be more slowly achieved.

## Improved Performance Case

It is expected that the installation of the larger tubewells will always attract a greater degree of HMGN assistance than STWs. It is likely, therefore, that the improved performance levels of production will be reached quickly compared to STWs, and more quickly than rainfed cropping can be expected to improve to the future rainfed position described in earlier chapters. For MTWs and DTWs to achieve the incremental benefits shown in Columns 3 and 6 of Table 6.3 could take six years at the rate below:

Year	1	2	3	4	5	6
Percentage of full incremental benefit	15	30	55	80	95	100

The Base Case can be considered to represent performance with rather little outside support, though more than STWs have been getting. The improved performance case assumes that the tubewell groups receive good support from the beginning.

Year	1	2	3	4	5	6
Percentage of full incremental benefit	15	30	55	80	95	100

## CHAPTER 7

### TUBEWELL COSTS

#### 7.1 Introduction

The expected benefits from shallow, medium and deep tubewells given in the two previous chapters are for before the deduction of fixed production overhead costs. The cost of providing irrigation water is the major fixed cost and is presented in this chapter. The background to the technical possibilities for the three tubewell types and the detailed breakdown of capital and recurrent costs for the tubewells are given in Volume 3, Groundwater, and for distribution systems in Volume 4, Engineering. The costs for the tubewell variants considered most appropriate to the range of analyses described in Chapter 2 (Tables 2.3 and 2.4) are summarised in this chapter.

Financial and economic prices are presented using the economic conversion factors for each of the major well cost components for each of the major wells. Cost components are discussed in Chapter 3.

#### 7.2 Shallow Tubewells

##### 7.2.1 Capital Costs

##### (a) Well and Pumpset

Three types of well were considered: mechanically drilled as provided under the ILC programme, manually drilled as generally supplied with ADBN financing and the smaller capacity hand dug well found in areas with shallow aquifers and suitable soil conditions. In each case, suction mode diesel powered pumpsets are included. The cost of both gravel packed and natural development of the mechanically drilled boreholes were also considered.

The pumpset capacities adopted were 13 l/s for the ILC and ADBN type wells and 10 l/s for hand dug wells.

The costs are broken down in Table 7.1 for machine drilled wells; in Table 7.2 for manually drilled wells and in Table 7.3 for hand dug wells. Each table sets out the main cost components and conversion factors used.

The costs are summarised to more clearly show the foreign exchange (FE) element in Table 7.4.

**TABLE 7.4**

**Summary of Shallow Tubewell Costs at 1993 Prices (Rs '000)**

TW type	Financial			Economic				
	Foreign exchange	Local costs	Unskilled labour	Total	Foreign exchange	Local costs	Unskilled labour	Total
Diesel/suction mode/ manually installed								
- hand drilled	36.80	12.32	2.48	51.60	27.04	11.59	1.86	40.49
- hand dug (10 l/s)	20.00	6.94	11.16	38.10	14.00	6.27	8.37	28.64
Electric/suction mode*				141.60				114.33
Diesel/suction mode/ machine drilled								
development								
- natural	81.10	155.07	12.20	248.37	62.48	141.51	9.15	213.14
- gravel pack	79.63	169.62	12.63	261.87	61.30	153.97	9.47	224.74

Notes: \* including electrical connection costs of Rs 76 000 (Rs 63 080 economic) assuming one 11 kV/400 V transformer shared between 4 STWs.

Source: GDC estimates (Appendix F and Volume 3, Groundwater)

The total costs and FE proportion are:

Pricing	Machine drilled		Manually drilled natural development	Hand dug
	Gravel pack	Natural development		
<b>Financial (Rs'000)</b>	261.87	248.37	51.60	38.10
<b>FE (%)</b>	33	36	71	53
<b>Economic (Rs'000)</b>	224.74	213.14	40.50	28.64
<b>FE (%)</b>	30	32	68	49

The costs include borehole, pumpset and pumphouse of the standard commonly found with the type of tubewell costed. Details of these are given in Volume 4 and the costs are shown in Tables 7.1 to 7.3.

While innumerable variations of STW could be compared, only two comparisons have been made: between the three methods of drilling and between gravel packed and naturally developed machine drilled STWs.

### Drilling Methods

The capital and discounted costs of the different STW drilling methods are summarised below:

Item	Initial cost (Rs '000)		NPV at 12% - 20 years (Rs '000)	
	Financial	Economic	Financial	Economic
Hand dug drilled	38.10	28.64	50.50	38.19
Natural development				
- Manual	51.60	40.50	65.84	51.51
- Machine	248.37	213.14	258.44	220.66
Gravel pack machine	261.87	224.74	272.32	232.58

The calculations use the following assumptions:

Item	Life period (years)
Pump	10
Motor	8
Well	
- hand dug	8
- manually drilled	10
- machine drilled	15
Pumphouse	20

Annual maintenance costs have also been included for hand dug wells at 5% of the well cost. No similar cost would be incurred for the bore holes. The residual values of the pumps, motors and wells are also allowed for in year 20 based on the proportion of expected component life remaining at that time.

The costs are compared for each unit area of land irrigated in Table 7.5.

**TABLE 7.5**

**Comparison of Diesel Driven Shallow Tubewell Costs (Rs '000/ha)**

Drilling method	Capital cost		NPV (12%-20 years)	
	Financial	Economic	Financial	Economic
Hand dug	12.7	9.6	16.8	12.7
Drilled				
Manually drilled	12.9	10.1	16.5	12.9
Machine drilled				
- natural development	62.1	53.3	64.6	55.2
- gravel pack	65.5	56.2	68.1	58.1

Source: GDC estimates

Both the ILC (machine) and ADBN (manual) type STWs have the same capacity and with reasonable management could serve 4 ha. The smaller hand dug wells can be expected to irrigate 3 ha and the smaller command area served by hand dug wells and their shorter life reduces their apparent slight cost advantage over the ADBN type naturally developed, manually drilled wells. Over 20 years there is a negligible difference in cost between the hand dug and manually drilled STWs.

The ADBN type STW is substantially cheaper for each hectare command area over a 20 year period than machine drilled wells:

Type of development	Manual natural (ADBN)	Machine (natural development)	Machine (gravel pack) (ILC)	Hand dug
Financial (%)	100	392	412	102
Economic (%)	100	428	450	99

(NPV 12% and 20 years comparison)

Clearly where circumstances permit, the manually drilled, naturally developed STW should be favoured.

#### Method of Borehole Development

The figures given indicate that there is a slight (5 to 6%) cost advantage when boreholes are naturally developed (Table 7.1) rather than gravel packed.

#### (b) Distribution Systems

Open channel distribution systems are appropriate to STWs. Table 7.6 summarises the costs of lined and unlined earth systems described in Volume 4, Engineering. The ILC programme uses the more expensive lined system while ADBN and privately funded STWs typically have earth channels, which exhibit greater water losses on most soil types.

It has been assumed for the unlined channels that the STW owner's family or group carry out the construction. Therefore, no cost was included in the financial analyses. In the economic analysis, the opportunity cost of labour need for construction has been used and the CF of 0.75 (refer to Section 3.8.2) for unskilled labour has been applied to the financial seasonal wage rates applied to local construction costs (Volume 4). No structures are included in typical unlined distribution systems.

System	Cost (US\$)	Notes
Lined earth	100	
Unlined earth	100	
Lined earth	100	
Unlined earth	100	

**TABLE 7.6**

CF	0.90	0.80	1.00	0.75	0.75
Economic	0	0	0	2 516	2 516

Notes: (1) Costs in this table are given at the prevailing seasonal wage; see text for cost of unskilled labour used in the financial analyses.

(2) no permanent structures built on ADBN type STWs.

Source: GDC estimates

Single brick width lined channels with the appropriate structures described in Volume 4 are expected to be constructed using 50% hired labour, the cost of which has been included in the financial analyses, and 50% farmer's family labour which has been excluded though included in the economic analysis at its shadow price.

The figures used in the analyses, after making these adjustments to those in Table 7.6 are:

	Unlined (Rs/ha)	Lined (Rs/ha)
Financial	-	32 810
Economic	2 520	29 680

## 7.2.2 Recurrent Costs

### (a) Pumping

The cost of diesel and electric STW pumping has been discussed in Volume 3, Groundwater. The prices of diesel fuel and electrical energy were presented in Section 3.12 of this volume. Diesel cost varies across the Study Area and the differences are taken into account in the annual operating costs presented in Table 7.7. The table sets out the annual energy costs for one hectare assuming the pumping hours necessary with lined and unlined open channels, for the main and inner Terai conditions, and on the basis of the base crop cropping patterns described in Section 5.2. The total pumpset operating costs shown in Table 7.7 include an element of minor repairs and regular maintenance at 10% of the initial pump capital cost a year spread over the actual irrigated area.

The hours pumped will vary not only between the main and Inner Terai but also as crop performance and well utilisation improves. Tables 7.8 and 7.9 show the extent of the variations for each Study Area stratum for the improved performance and high utilisation cases (Section 5.2), respectively. The differences between the three cropping cases are illustrated in Table 7.10 for the Central (main Terai) and Inner Terai strata.

Dug well pumping hours have been increased by 50% over the STW levels for unlined channels to compensate for the reduction to 10 l/s and associated drop in system efficiency.

STW	Channel	Area (ha)	STW (l/s)	Hours (h)	Cost (Rs)	Total Cost (Rs)
100	Lined	100	10	100	1000	1000
100	Unlined	100	10	150	1500	1500
200	Lined	100	20	100	2000	2000
200	Unlined	100	20	150	3000	3000
300	Lined	100	30	100	3000	3000
300	Unlined	100	30	150	4500	4500

**(b) Distribution Systems**

Unlined earth channels can be maintained by unskilled family labour and therefore, no cost is shown in the financial analyses. In the economic analyses, it is expected that one-fifth of the system will require repairs and maintenance. This amounts to approximately 60 m/ha, equivalent to three days work at 10 m a day. At the shadow wage rate of Rs 26/day, the annual cost included is Rs 80/ha (Rs 78 rounded).

Lined systems require some financial expense even though repairs are likely to be carried out by family or group members since materials are needed for structures and channel linings. Maintenance costs, therefore, have been estimated at 3% of capital costs excluding unskilled labour each year, equivalent to Rs 915/ha (refer to Table 7.6). Based on the economic costs given in Table 7.6, the annual amount allowed at economic values is Rs 788/ha each year.

### (c) Other Recurrent Costs

Land tax is included at Rs 118/ha year. This represents payment for Abbal land which is irrigable the year round (Section 3.5).

Miscellaneous costs to cover farm tools, crop processing and storage, and other minor fixed overheads are allowed for at the rate of 5% of the variable costs of crop production derived from the base case cropping pattern in the Central Stratum. As shown below, this is almost Rs 175/ha a year.

Crop	Financial cost			Annual fixed costs (Rs/ha)
	Average all strata		Proportion factor	
	Total (Rs/ha)	5% (Rs/ha)		
Rice	4 670	234	0.53	124
Wheat	2 110	106	0.17	18
Maize	1 470	74	0.10	7
Oil seed	560	28	0.10	3
Pulse	410	21	0.05	1
Potato	9 620	481	0.04	19
<b>Total</b>			1.00	172

These costs are financial. The economic cost has been derived using the SFC of 0.9, Rs 158/ha.

## 7.3 Medium and Deep Tubewells

### 7.3.1 Introduction

Detailed specifications and costings for medium and deep tubewells with capacities ranging from 15 h/s to 90 h/s are given in Volume 3, Groundwater. Their capital and recurrent costs at 1993 financial and economic prices are summarised in the next two sections. Section 7.3.4 presents the results of face-level cost comparisons in terms of the unit cost of water at the wellhead. The comparisons are:

- (1) diesel versus electric pumping;
- (2) gravel pack versus natural borehole development;
- (3) siting in D1, D2, or D3 aquifers.

The three comparisons are summarised as shown in Table 7.11.

**TABLE 7.11**

**Medium and Deep Tubewell Least Cost Comparisons**

Comparison	Pumpset power	Type of well completion	Aquifer class	Pumpset mode	Tubewell capacity				
					90 l/s	60 l/s	45 l/s	30 l/s	15 l/s
Diesel v electric	diesel electric	gravel pack	D2	force	*	*	*	*	*
Well completion	diesel	gravel pack natural dev	D2	force	*	*	*	*	*
Aquifer class	diesel	gravel pack	D1 D2 D3	force	*	*	*	*	*

The tubewell sizes and basic specifications and aquifer classes for which each comparison is made are set out in the tables.

Section 7.3.5 provides the cost of, and comparison of two types of water distribution systems suitable for MTWs and DTWs: lined open channels and piped systems.

The main financial and economic analyses combining costs and benefits are provided in Chapter 9.

### 7.3.2 Capital Costs

Table 7.12 summarises the financial and economic capital costs for MTW and DTW boreholes, force mode pumpsets and pumphouses for wells of the capacity 90, 60, 45, 30 and 15 l/s in D2 aquifers. In each case the cost of diesel and electric versions and for gravel packed and naturally developed boreholes are shown. Electrically powered tubewell costs include provision for equipment, and power lines from 11 kV transmission lines as described in Volume 4, Engineering.

The cost of installing the different capacity diesel powered, gravel packed force mode MTWs and DTWs in D1, D2, and D3 class aquifers is summarised in Table 7.13.

Well costs are based on current construction practices and do not reflect the economies in construction of lower capacity wells thought to be attainable by using cheaper materials.

Miscellaneous costs of 10% representing engineering costs have been added to both Tables 7.12 and 7.13.

### 7.3.3 Pumping Costs

Tables 7.14 and 7.15 set out the hourly diesel and electric pumping costs. These were derived from the energy prices discussed in Section 3.12 and consumption rates given in Volume 3, Groundwater, for the different tubewell sizes. Regular repair and maintenance costs have been included at 10% of original capital cost on an hourly basis. the annual operating hours shown in Table 7.14 are based on usage in the main Terai with land open channel distribution systems and providing for the Improved Performance cropping pattern presented in Chapter 6.

### 7.3.4 Tubewell Comparisons

The three comparisons summarised in Table 7.11 have a numbers of assumptions in common. These include the following replacement periods (years):

	Diesel				Electric			
	Gravel pack		Natural development		Gravel pack		Natural development	
Borehole	20		20		20		20	
Pump	10	)	10	)	10	)	10	)
		) 8*		) 12*		) 12*		) 12*
Motor	7	)	7	)	15	)	15	)
Pumphouse	20		20		0		20	

Note: \* aggregate 8 year replacement period

These periods are before replacement or a major refit. The comparisons are each made in terms of water pumped at the wellhead areas discounted over a 20 year period using the pumping costs given in the previous section for each well size and type.

In the year of installation, it has been assumed that the well operates for half the full year's annual hours.

#### Diesel versus electric power

The cost of water at the wellhead for the five different size MTWs and DTWs is shown in Table 7.16. The costs shown are the NPV (12%) of one cubic metre of water over a 20 year period.

- 60 l/s	0.276	0.392
- 45 l/s	0.302	0.409
- 30 l/s	0.321	0.333
- 15 l/s	0.365	0.405

**Note:** Gravel packed wells in D2 aquifer with force mode pumps

**Source:** GDC estimates

At present financial prices, the unit cost of water varies from Rs 0.318 to Rs 0.431/m<sup>3</sup> from the 90 l/s to the small 15 l/s wells and the cost as might be expected falls as well size increases. Electric pumpsets, because of different connection and equipment requirements, do not show the same pattern. At the subsidised NEA rates discussed in Volume 3, Groundwater, the cost of water varies from Rs 0.401/m<sup>3</sup> for 45 l/s MTWs to Rs 0.313/m<sup>3</sup> for the 30 l/s MTW. Costs are higher than diesel by 17 to 20% or more for tubewells of 45 l/s but in contrast, cheaper for the smaller tubewells; 15% less in the case of 30 l/s tubewells and 5% less for the small 15 l/s example.

The analyses using economic values that exclude subsidies show that water is more expensive for all MTW and DTW sizes if delivered using electric pumpsets. This reflects the impact of charging the full well connection cost. The cost advantage to diesel varies as shown in Table 7.16 from 41% for 90 l/s DTWs to only 4% for the 30 l/s model. Generally the cost advantage decreases with well capacity as illustrated in the table.

## Borehole Development

Gravel pack and naturally developed boreholes have a similar life and well maintenance costs are minimal in both cases. At both financial prices and economic values, gravel pack boreholes are a lot more costly over a 20 year period. Water costs are 7% (15 l/s and 30 l/s MTW) to 9% (90 l/s DTW) more expensive with gravel pack wells.

As shown in Table 7.17, there is, therefore, a slight but not very significant advantage in the natural development of MTWs and DTWs whatever their capacity.

**TABLE 7.17**

**Comparison of Water Costs from Gravel Pack and Natural Well Development (Rs/m<sup>3</sup>)**

MTW/DTW size	Gravel pack	Natural development
<b>Financial</b>		
- 90 l/s	0.318	0.292
- 60 l/s	0.319	0.302
- 45 l/s	0.344	0.319
- 30 l/s	0.369	0.344
- 15 l/s	0.431	0.404
<b>Economic</b>		
- 90 l/s	0.282	0.258
- 60 l/s	0.276	0.262
- 45 l/s	0.302	0.280
- 30 l/s	0.321	0.299
- 15 l/s	0.365	0.342

Note: Gravel packed wells in D2 aquifer with force mode pumps

Source: GDC estimates

## Aquifer Class

The cost of water extraction for the three aquifer classes; D1, D2 and the deepest D3; are given in Table 7.18.

**TABLE 7.18**

**Comparison between DTW/MTW Water Costs from Aquifer Classes D1, D2 and D3  
(Rs/m<sup>3</sup>)**

MTW/DTW size	D1	D2	D3
<b>Financial</b>			
- 90 l/s	0.289	0.318	<b>0.368</b>
- 60 l/s	0.303	0.319	
- 45 l/s	0.323	0.344	
- 30 l/s	0.355	0.369	
- 15 l/s	0.414	0.431	
<b>Economic</b>			
- 90 l/s	0.259	0.282	0.324
- 60 l/s	0.263	0.276	
- 45 l/s	0.285	0.302	
- 30 l/s	0.310	0.321	
- 15 l/s	0.351	0.365	

**Note:** Gravel packed wells with diesel driven pumps

**Source:** GDC estimates

The main analysis has been based on MTWs and DTWs sunk in D2 aquifers. However as shown in the table, and to be expected the cost of water extracted from more productive D1 aquifers is 4 to 9% lower at financial prices. The difference as shown below is greatest in the case of the largest DTWs:

Difference in cost (financial)	DTW capacity (l/s)				
	90	60	45	30	15
D1	91	95	94	96	96
D2	100	100	100	100	100
D3	116	-	-	-	-

Only the 90 l/s DTW was analysed for the D3 aquifer case and the cost of water rises from Rs 0.318/m<sup>3</sup> to Rs 0.368/m<sup>3</sup> making it 16% more expensive. In practical terms, we would not recommend siting wells in D3 aquifers; certainly not for the larger capacity wells which would attract heavy pumping cost penalties.

The pattern and size of the cost differences are the same at economic values. The results in Table 7.18 depict the classical view that water costs increase with decreasing pump size. If more innovative (and cost saving) well design is championed, this view might change (with water from cheaper low capacity wells becoming more financially and economically attractive).

### 7.3.5 Distribution Systems

Three types of distribution system for MTWs and DTWs are discussed in Volume 4, Engineering; unlined and lined open channels, and buried pipes. The unit area costs for lined channels and buried pipes are given in Table 7.19. The piped systems are about 38% less expensive to install than lined channels. They are easy to maintain and provide water "on tap" which makes for easier water management provided that the design is sound and the recipient farmers cooperate with each other. Unlined earth channels are not normally considered in the context of MTWs/DTWs.

**TABLE 7.19**

**Capital Costs of DTW/MTW Distribution Systems (Rs/ha)**

System type	Local materials	Imported materials	Skilled labour	Unskilled labour (2)	Total cost
(a) Piped systems (1)					
Cost factor	0.15	0.73	0.06	0.06	1.00
Financial cost	3 330	16 206	1 332	1 332	22 200
CF	0.90	0.80	1.00	0.75	0.82
Economic cost	2 997	12 965	1 332	999	18 293
(b) Lined open channels					
Financial cost	12 311	15 176	3 041	4 561	35 090
CF	0.90	0.80	1.00	0.75	0.85
Economic cost	11 080	12 141	3 041	3 421	29 682

- Notes: 1. Average for ring main and radial systems.  
2. See Table 7.6

Source: GDC estimates

The costs compare as shown below:

Item	Financial		Economic
	(Rs '000/ha)	(FE %)	(Rs '000/ha)
Lined open channels	35.09	43	29.68
Piped systems	22.20	73	18.29

Piped systems do however have a much higher foreign exchange component; 73% against 43%. Piped systems when reasonably operated also reduce water losses and reduce pumping requirements by about one quarter.

A simple analysis was performed to compare the net present value (NPV) of costs of the distribution systems, annual maintenance (taken as 3% of the capital cost for both piped systems and lined open channels) and the annual pumping costs discounted at 12% per annum over a period of 20 years. When expressed as an annual cost per hectare over the 20 year period the results averaged:

Pricing	NPV (12%) (Rs '000/ha per year)		Ratio of lined/piped
	Lined channels	Buried pipes	
Financial	1.91	1.20	1.59
Economic	1.62	1.00	1.62

The life of both lined channel and piped systems was taken as 20 years. Pumping costs for the piped systems were increased by a nominal 15% to allow for higher delivery head at the pump.

## CHAPTER 8

### SHALLOW TUBEWELL ANALYSES

#### 8.1 Scope

Two sets of analyses were carried out. The first presented in the following section is to compare machine and manually drilled shallow tubewells and hand dug wells. The second is to examine the differences in financial returns to the farmers and the economic benefits from the most widely used manually drilled, diesel powered STWs in the four different Study Area strata.

#### 8.2 Well Type Comparison

##### 8.2.1 Introduction

The two STWs included in this comparison can be viewed as the ILC and ADBN models. The ILC model is machine drilled, gravel packed and with a lined water distribution system. It typically serves 4 ha, though with good water management and larger group ownership, this could practically be raised to an average 7 ha. In contrast, the ADBN manually drilled, naturally developed type that has an unlined, earth distribution system has been found to irrigate between 1.9 ha (West stratum) and 2.5 ha (Inner Terai). With improved water management, this can be increased to at least 4 ha. Throughout the Study Area where aquifers are shallow, there are hand dug wells that may irrigate 2 to 3 ha via unlined systems.

The comparison made is for conditions (pricing, cropping, etc.) in the Central Stratum that were described in an earlier chapter. In each case, suction mode diesel pumpsets are assumed.

Three comparisons are presented:

##### Base Case (BC)

The Base Case represents average performance and crop cultural practices as found at present (Volume 3, Groundwater; Volume 2B, Agriculture) and described in Chapter 5 of this volume.

##### Improved Performance (IP)

The Improved Performance Case represents the cultural and water management practices that could be practised given existing knowledge provided that farmers were made aware of it and had access to the necessary crop inputs. The IP case, however, assumes that the formation of larger owners' or users' groups remains a problem and the present level of well coverage remains as in the BC.

## High Utilisation (HU)

Finally, the High Utilisation case, which illustrates benefits from the IP case over a larger, but nevertheless, realistic command area. This may be viewed as a future case where support services are strengthened and more active in the field of water management and irrigated crop cultivation (Volume 2C, Social Studies) and where the benefits of group well ownership or water buying/selling are more widely accepted than at present.

The comparison between the three well types is presented in the form of internal rates of return (IRR), net present values (NPV) and benefit/cost ratios (B/C) over a 20 year period. The results are given at both 1993 financial prices and forecast (2005) economic values at constant 1993 prices. These were discussed in Chapter 3. Returns to farmers are shown in more detail in Chapter 8 in which the benefits to the ADBN type STW in each of the four Study Area strata are compared. A 12% discount rate was used in the analyses.

The major characteristics of the three wells are summarised in Table 8.1.

**TABLE 8.1**  
**STW and Hand Dug Well Characteristics, Central Stratum,**  
**Diesel Powered, Suction Mode**

Well type	Borehole development	Distribution system	Depth (m)	Command area (ha)	
				BC/IP*	HU
Drilled - machine (ILC) - manual (ADBN)	Gravel pack	Lined	60	4.0	7
	Natural	Unlined	20	2.3	4
Hand dug	**	Unlined	10	2.0	3

Notes: \* BC = Base Case; IP = Improved Performance; HU = High Utilisation (See text)  
\*\* Lined with concrete rings

### 8.2.2 Well Costs

The financial and economic capital costs are set out in Table 8.2. Details are provided in Volume 3, Groundwater, and Chapter 7. Table 8.3 summarises the annual recurrent costs for pumping and fixed overheads that covers distribution system maintenance, land tax and the miscellaneous items noted in Chapter 7.

TABLE 8.2

**Summary of STW and Dug Well Capital Costs; Central Stratum,  
Suction Mode, Diesel Powered (Rs '000)**

Well Type	Well and pumpset	Distribution system		Total		Unit area cost (Rs 000/ha)	
		BC/IP	HU	BC/IP	HU	BC/IP	HU
<b>Financial</b>

(1) gravel pack development; (2) natural development

Source: GDC estimates

### 8.2.3 Benefits

The derivation of the incremental crop benefits, expressed as gross margins, has been given in Chapter 5 and Appendix D. The benefits in the Central Stratum for various cases compared are summarised in Table 8.4. The unit area gross margins net of the returns from an equivalent area of rainfed crops are:

Case	Financial (Rs/ha)	Economic (Rs/ha)
Base case	7 320	7 500
Improved performance	14 580	17 210
High intensity	14 050	16 660

Source: GDC estimates

The IP figures are net of present rainfed production levels while the HI returns are net of the forecast future rainfed cropping performance that has been discussed in Volume 2, Part B, Agriculture.

In the analyses, allowance has been made for the farmers' adjustment to the new, irrigated production regime. In the BC, this will be rapid since no new non-water cultural practices or substantially different levels of inputs are envisaged. A longer period to build up the "full development" yields and practices is expected for the IP and HI cases. The build up rates for full, two season years adopted were:

% full production	1	2	3	Year 4	5	6	7
BC	60	100	100	100	100	100	100
IP/HI	50	55	65	70	85	90	100

In the year of installation, 50% of the first full year benefits have been assumed.

#### 8.2.4 Results

The results of the analyses are set out in Table 8.5.

**TABLE 8.5**

**Summary of Shallow Tubewell Economic Analyses at 1993 (Prices)  
(Central Stratum)**

Well type	Economic analyses		
	IRR (%)	NPV (Rs'000)	B/C ratio

Source: GDC estimates

The apparent advantage of cheap hand dug wells is interesting. Such wells installed where groundwater is shallow and percolation/recharge reasonable and where STWs are hard to install are attractive. Even with Base Case cropping the IRR reaches 14% with a B/C ratio of 1.04. The analysis is vulnerable to variations in well depth, digging conditions and the ability of the wells to sustain continuous pumping; STWs will be more capable of withstanding variations in watertable. In good conditions however, dug wells can perform very effectively.

Both the ILC and ADBN model STWs as specified for the analyses give unfavourable economic returns under present average cropping practices with the areas now typically irrigated from them. Even under IP cropping with its higher yields and returns the ILC model fails to reach the 12% IRR target (with 8.4% IRR and 0.85 B/C ratio). This reinforces the need to concentrate on expanding actual irrigation coverage to the 7 ha average target.

The standard manually drilled ADBN STWs will give acceptable economic returns, however, if crop cultivation practices are improved to the extent discussed in Chapter 4 and Volume 2B, Agriculture. With large (HU Case) command areas and IP benefits, ILC and ADBN STWs are likely to be economically viable as Table 8.5 shows. The key results of this analysis therefore clearly favour hand dug wells for very shallow aquifers and ADBN type manually drilled STWs with unlined distribution systems elsewhere, unless groundwater is at depth or in strata more technically suited to the more costly machine drilling practised by ILC. It is assumed that groundwater exploitation in the Study Area would be concentrated on the more favourable areas suited to manually drilled STWs unless farmers' demand was found to be particularly strong in other areas. Therefore, the following section of the analysis which compares returns to STWs throughout the main and inner Terai is based on the manually drilled model described above. It should be noted that while the machine and manually drilled STW models have been referred to as typical of the ILC and ADBN programmes, the results cannot be taken as detailed enough to provide any firm analysis of either programme's success or lack of success.

### **8.3 Study Area Shallow Tubewell Returns by Stratum**

#### **8.3.1 Introduction**

As noted in Section 8.1, the comparison of returns to STWs in the four Study Area strata have been assessed on the basis of manually drilled boreholes, diesel pumpsets and unlined distribution systems. The analyses are to illustrate the differences across the Study Area taking into account the main variations in farmers' circumstances arising from their location and general climatic and other environmental conditions. These are reflected in the prices, cropping patterns and crop yields that were discussed earlier in this volume and in Volume 2, Land Resources and Agriculture.

#### **8.3.2 Capital Costs**

The cost of manually drilled STWs given in Section 8.2.2 (Table 8.2) has been used for all strata. While there will be some variation, these may be small and have been ignored bearing in mind the scale and scope of the study.

### 8.3.3 Recurrent Costs

Differences in fuel prices within the Study Area are taken into account in the annual pumping costs that are summarised in Table 8.6. Water requirement and pumping hour estimates are discussed in Volume 3, Groundwater. In general, requirements are significantly lower in the Inner Terai. They vary also from the east to the west of the main Terai, but less significantly. As shown in Table 8.6 one set of pumping hours has been used for the main Terai.

The other recurrent costs shown in Table 8.7 are as described for the previous STW analyses in Section 8.2.2.

### 8.3.4 Benefits

The incremental crop benefits and their build up for each analysis stratum and cropping case are given in Table 8.8. Their derivation has already been described and details are given in Appendix D.

## 8.4 Economic Analysis by Stratum

The analysis shows that returns to STWs under present conditions, the Base Case, are substantially better in the East and Inner Terai strata than elsewhere. In the West and Central strata, they are at best marginal with B/C ratios of 0.9 and 0.93 and IRR of 6 and 8%, respectively. Table 8.9 summarises the results.

### Base Case

The Base Case results are of particular interest since they illustrate the effect of STW irrigation under present conditions. Farmers react to the availability of year round water within the limits imposed by their own and their area's particular conditions (price, input suppliers, market accessibility, etc.) and without significant HMGN or other support.

The Base Case clearly shows that economic returns to STWs are good in the East and Inner Terai strata, marginal in the Central and poor in the West.

Stratum	Economic	
	IRR (%)	B/C (ratio)
West	5.7	0.89
Central	8.1	0.93
East	38.0	1.54
Inner Terai	22.3	1.22

Tables 8.10 and 8.11 illustrate some of the critical changes that occur in each of the four strata when STWs are installed. It can be seen from Table 8.10 that one major factor in the different results is the substantial rise in cropping intensities in the East (59%) and Inner Terai (87%) compared to 38% in the West and a very modest 19% in the Central stratum. In addition in the West, an average area irrigated is less than two hectares (1.9 ha) in contrast to 2.3 to 2.5 ha elsewhere.

**TABLE 8.10**

**Comparison of Changes with STW Irrigation in the Study Area**

Stratum	STW area (ha)	Annual cropping (%)		Cropping change (%)
		rainfed	irrigated	
West	1.9	143	197	38
Central	2.3	171	204	19
East	2.3	129	205	59
Inner Terai	2.5	91	170	87

Source: Chapter 5 and Volume 2B, Agriculture

Except in the Central stratum, the area of wheat grown rises considerably from 220% (East) to 335% (Inner Terai), and Table 8.11 shows that the pattern is similar for vegetables. In the Central stratum, farmers grow larger areas of these two crops rainfed than elsewhere, which accounts for the lower increase when irrigation is available. The increased area of paddy grown is substantial in the Inner Terai (+132%), low in Central (3%) where it is grown rainfed on a large scale and moderate in the other two strata.

**TABLE 8.11**

Source: Chapter 5 and Volume 2B, Agriculture

These differences in response to the use of STWs combined with generally rather low costs in the East stratum account for the very significant contrast in economic benefits. The differences can crudely be summarised as follows:

Ranking	Stratum	STW command area	Change in cropping intensity	Increase in crop area		
				Paddy	Wheat	Vegetables
1	East	M	VH	L	H	VH
2	Inner Terai	M	H	M	H	VH
3	Central	M	VL	M	L	M
4	West	L	L	M	H	H

Notes: L = low, M = medium, H = high, and V = very

### Improved Performance

Conditions in the main and inner Terai give rise to very good irrigated production potential (Volume 2, Parts A and B). However, the study's social and institutional investigations show that support services and their ability to extend new ideas and techniques to farmers are poorly developed throughout the Study Area. This is particularly noticeable in the case of irrigated cropping. The move from rainfed to irrigated production requires considerable practice to realise the new situation's potential.

The requirements and possibilities discussed earlier in the report could result in the economic returns shown in Table 8.9 without any increase in STW command areas. Assuming a seven year period before a farmer reaches the full levels of output, assumed economic IRRs would vary from 41% in the Central to almost 70% in the Inner Terai with B/C ratios of 1.8 to 2.7, respectively.

If in addition, STW command areas can be increased from the present 1.9 to 2.5 ha range to 4 ha, STWs could become extremely attractive in all strata as shown for the high intensity case in Table 8.9. Benefit/cost ratios could rise to between 2.5 to 3.9. The assumptions underlying this future possibility are considered reasonable and practical but cannot be expected, except in the case of particular farmers, until support services, from DOI and DOA in particular, are improved.

The IP and HU case economic returns to STWs therefore can be considered as an indication of the medium term prospects to the sector.

## 8.5 Financial Analysis

### 8.5.1 General

STWs are considered in this section on the basis of the net income levels that can be expected in each study stratum at present and future levels of crop production - the Base and Improved Performance cases and also from a 4 ha area, the High Utilisation case.

The first analysis, however, is presented in terms of NPV - B/C and IRR at financial prices which gives a broader view of the financial value of STWs in the four Study Area strata.

### 8.5.2 Costs and Benefits

The total financial cost of manually drilled STWs has already been given. Farmers are able through ADBN to receive a substantial subsidy of 40% as an individual and 70% if bought by a group of four and more persons. The capital costs in these circumstances fall from Rs 51 600 to Rs 30 960 at 40% subsidy and Rs 15 480 at the 70% group subsidy rate.

The benefits used in the analysis are the full crop gross margins, that is, not net of the value of rainfed production from the same area. These are given below:

Stratum	Rs/ha		
	Base Case	Improved performance	IP + High Utilisation
West	12 320	20 290	21 340
Central	16 400	26 180	25 640
East	16 210	25 680	25 020
Inner Terai	12 180	21 860	24 220

The benefit flow is set out in Table 8.12 using the same build up periods as before.

### 8.5.3 Basic Analysis

Using the full crop gross margin benefits, the financial viability of STWs is good throughout the Study Area; this is true even at Base Case cropping and command areas and taking into account the full, unsubsidised cost of the STW. The BC analysis results with and without HMGN subsidies are given in Table 8.13.

**TABLE 8.12**

#### 8.5.4 Returns to the Farmers

The returns more relevant to the STW owner have been assessed for each strata in terms of their likely loan repayment capacity. The basic assumption has been that the net value of production would have to be increased by 25% above pre-STW levels for the area that is irrigated by the STW before loan repayments would willingly be paid. Since data available for the study did not include farmers' views on this, the adopted minimum increase is necessarily an arbitrary one.

It is based on the following three considerations:

- (a) STWs are well known in most areas of the Terai and are generally known to be reliable in operation. The level of confidence in them is good and the perceived investment risk is lower than would be the case with any irrigation system known to be unreliable. This applies under Terai conditions to many surface irrigation schemes where the date of the arrival and period of water availability is uncertain as it is dependent on the seasonal variations each year.
- (b) An allowance has been made for the insurance effect against crop damage by dry periods in the main monsoon season and against low levels of residual moisture for the second winter crop season. As the LRMP study showed, a second, winter season crop is grown by many farmers throughout the Terai but, without irrigation, results are precarious owing to possible late planting and low soil moisture content.

These aspects have some value to farmers and lead to the adoption of a minimum expected increase in net farm income of 25% from irrigation.

The net income increases calculated for the BC in each stratum are summarised in Table 8.14 using data in Appendix D and Chapter 7. In the first year of installation, it has been assumed that the well operates for 30% of the time; in year two, 60% of the time; and the final benefits from year three are forecast, as in the earlier analyses. It is clear that with the exception of West stratum the increase in net income exceeds the extra 25% minimum. In the West it would be 18% extra each year. On this basis the funds possibly available for loan repayment from the second full year of operation would be as follows and detailed in Table 8.15.

Stratum	Rs/year
West	nil (-780)
Central	1 500
East	8 780
Inner Terai	8 220

TABLE 8.14

- Increase Rs/unit	-637	-1 275	10 903	
- Increase x	0.88	0.88	2.02	

Note: (1) Assume 30% income in the installation year

Source: GDC estimates

If the IP production levels could be reached in three years, in contrast to the seven year assumption used in the previous analyses, then repayment levels would rise substantially to those in the second part of Table 8.15 which are:

Stratum	Rs/year
West	10 280
Central	10 420
East	25 140
Inner Terai	29 530

This may be a possibility in the future when full, effective irrigation support services are available. The IP figures therefore assume that rainfed production is also greater to the extent described in Chapter 4.

**TABLE 8.15**

Notes: \* Target income before funds available for loan repayments taken as 125% of without STW income;

\*\* At full development, for assumptions see text.

## CHAPTER 9

### DEEP TUBEWELL ANALYSIS

#### 9.1 Scope

Table 9.1 summarises the full benefit/cost analyses carried out to assess the viability of medium and deep tubewells. All analyses are made for a DTW of 60 l/s capacity with a gravel packed borehole in a D2 aquifer and an open channel lined distribution system. This is sufficient under reasonable water management to serve a command area of 48 ha (at 1.25 l/s per hectare).

**TABLE 9.1**

**Medium and Deep Tubewell Analysis Characteristics**

Well capacity (l/s)	Distribution system	Command area (ha)*	Cropping level	Stratum (Terai)	Price basis	Land System		
						2M (mixed)	2U (upland)	2R (lowland)
60	Open Lined	48/52	Base	Main	finan	*		
				Inner	econ	*		
			Improved	Main	finan	*	*	*
				Inner	econ	*		

Note: \* 52 ha for Land System 2 upland, 48 ha for other classes

Source: GDC.

Economic analyses are provided to compare the following:

**Land Classes:** Classes 2 mixed, 2 upland, and 2R low land in the Main Terai, assuming the Improved Performance cropping level.

**Main and Inner Terai:** on Land Class 2, mixed for both the Base Case and Improved Performance cropping levels.

Details of the cropping patterns, yields, etc., for the different and land classes and cropping levels have already been presented in Chapter 4 and 6 based on details in Volume 2, Parts A and B, Land Resources and Agriculture.

Financial analyses cover only the main Terai, Land Class 2 mixed for Base and Improved Performance cropping. As for STWs (Chapter 8), the results are given in terms of NPV-B/C and IRRs and also, secondly, to show the net incomes that can be expected to accrue to farmers in MTW and DTW groups.

## 9.2 Costs

Table 9.2 summarises the capital costs for the 60 l/s DTW used in the analyses.

TABLE 9.2

**Deep Tubewell (60 l/s) Capital Costs**  
**Diesel, Gravel Pack, Lined Distribution System (Rs '000)**

Pricing	Land Class (1)	Command area (ha)	Well and pumpset	Distribution system	Total
Financial	2M/2RL	48	1 146.38	1 684.32	2 830.70
	2U	52	1 146.38	1 824.68	2 971.06
Economic	2M/2RL	48	954.34	1 424.74	2 379.08
	2U	52	954.34	1 824.68	2 779.02

Note: (1) 2M = Class 2 mixed, 2U = Class 2 upland, 2RL = Class 2 lowland

The annual recurrent costs are set out in Table 9.3. Both sets of costs are derived from figures given earlier with a number of adjustments for pumping hours required for the different land classes and the two areas covered the main and inner Terai - and the size of command area. This is larger, 52 ha for Class 2 upland than for the other two classes (48 ha). Full details of pumping requirements and DTW coverage are given in Volume 3.

## 9.3 Benefits

The benefits from MTW and DTW cropping for the three land classes and the differences between the main Terai and the inner Terai were given in Chapter 6.

From the unit area figures given in Table 6.2, the total incremental crop gross margins were as shown in Table 9.4 for the DTW cases in the analyses. Table 9.5 sets out the total (not incremental) financial gross margins used to determine farmers' net income position discussed in Section 9.5.

The two tables also show the anticipated build up of benefits from the year the tubewells are installed. These are as discussed in Section 6.3.

Source: GDC estimates

## 9.4 Economic Analysis

The results of the economic analyses are summarised in Table 9.6.

**TABLE 9.6**

### Summary of Deep Tubewell Economic Analyses

Case	Land system*	IRR (%)	NPV (Rs'000)	B/C ratio
Base (present)				
Main Terai	2M	5.48	-851	0.73
Inner Terai	2M	11.5	-71	0.98
Main Terai	2M	22.51	1 860	1.57
Inner Terai	2M	29.04	3 142	2.03
Main Terai	2U	20.13	1 594	1.48
Main Terai	2R	6.64	782	1.22

Note: \* 2M = System 2 mixed; 2U = System 2 upland; 2R = System 2 lowland.

Source: GDC.

The comparison between the main and inner Terai areas shows that returns to DTWs on Land Class 2 mixed are highest in the inner Terai:

Item	IRR (%)	B/C (ratio)
Base Case		
Main Terai	5.5	0.73
Inner Terai	11.5	0.98
Improved Case		
Main Terai	22.5	1.57
Inner Terai	29.0	2.03

As with shallow tubewells, this arises from the greater increase in cropping intensity with irrigation (91 to 195%, inner Terai; 146 to 195%, main Terai), rather higher unit area crop gross margins and lower water requirements.

The results, however, highlight the poor returns under present crop cultivation practices represented by the Base Case. The good results under the Improved Performance case cropping nevertheless shows that MTW and DTW irrigation in both the Terai areas is economically worthwhile, with IRRs of 22% to 29% and B/C ratios of 1.6 to over 2.0.

The main Terai analyses compare economic benefits from the three main land classes under likely future (improved performance) cropping, firstly the widely-occurring Class 2 Mixed (see Section 6.1); secondly Class 2 Upland areas where rice production is not possible and a maize-wheat pattern predominates; and finally Class 2R Lowland areas where cropping is very restricted and water requirements early in the monsoon high.

The three classes compare as follows:

Land class	IRR (%)	B/C (ratio)
2 Mixed	22.5	1.57
2 Upland	20.1	1.48
2R Lowland	16.6	1.22

As discussed in Volume 2, Land Resources and Agriculture, there are substantial areas of Class 2 mixed land, and the results confirm that they should be given first priority for groundwater development. Apart from the better economic returns, such areas are versatile in terms of cropping diversification where circumstances allow for it.

## 9.5 Financial Benefits

### 9.5.1 General

Medium and deep tubewells benefit groups of farmers. One of the characteristics of such groups when freely formed would probably be that they are members of communities who are more willing than most to adopt new ideas and cooperate in the ways necessary to jointly operate a command area of 12 to 70 ha and more. The more likely level of cropping that they will practise is represented by the Improved Performance case. As illustrated in Table 9.7, this will result in the excellent returns presented below. Returns assuming lower cropping and water management standards, the Base Case, are also given.

**TABLE 9.7****Summary of Deep Tubewell Financial Analyses 60 l/s (1993 prices)**

Case	Land class (1)	IRR (%)	NPV (Rs'000)	B/C ratio
Base (present)	2M		455	1.12
Main Terai		14.6	148	1.04
Inner Terai		12.9		
Improved (future)	2M	24.3	2 609	1.67
Main Terai		24.4	2 597	1.71
Inner Terai				

Note: (1) 2M = Class 2 mixed

Source: GDC estimates

### 9.5.2 Basic Analysis

Table 9.7 summarises the financial internal rates of return, and benefit-cost ratios calculated over a 20 year period using a discount rate of 12%. The flow of benefits used in the analyses was given in Table 9.5. These are the "gross" benefits - the crop gross margins in full, without deducting the value of crops previously grown, rainfed, in the DTW command area.

As with the economic analyses IP standard cropping results in good returns in both areas. The Present or BC level of yields and inputs, however, shows marginal returns, 12.9% IRR and 1.04 B/C ratio, in the inner Terai. The returns are better under main Terai conditions, 14.6% IRR and 1.12 B/C ratio.

### 9.5.3 Returns to Farmers

The returns to farmers at 1993 financial prices generally prevailing in the main Terai (Central stratum) and the inner Terai as summarised in Table 9.8 for the Base Case and Table 9.9 for Improved Performance cropping conditions. As noted earlier, these two cases incorporate assumptions to reflect the present levels of MTW and DTW cropping, yields, use of inputs and intensities, and BC and medium term future crop cultivation practices and results (IP case). The IP case incremental benefits are net of forecast future rainfed cropping which, as discussed earlier in this volume, gives rather higher yields than at present.

Source: GDC estimates

Assuming, as discussed in Section 8.5.4, that farmers would be unwilling to meet loan repayments before attaining a threshold income 25% higher than they are able under rainfed conditions, farmers in both the BC and IP cropping cases would have funds available to repay, in part or entirely, the capital cost of a 60 l/s DTW.

The levels of this annual "surplus" for repayments are shown in Table 9.10. In terms of repayment for each hectare and for the whole command area, these amounts are forecast to be:

Base Case	Year		
	2	3	4
<b>Main Terai</b>			
Ratio: irrigated to rainfed income	0.33	0.87	1.42
"Surplus" (Rs/ha)	-	-	1 350
(Rs/DTW)	-	-	64 700
<b>Inner Terai</b>			
Ratio: irrigated to rainfed income	0.57	1.45	2.33
"Surplus" (Rs/ha)	-	870	4 640
(Rs/DTW)	-	41 800	222 800

**TABLE 9.10**

**Summary of Improvement in Net DTW Income and Loan Repayment Capacity**

Case	Target income*	Year				
		2	3	4	5	6
<b>Base Case (present)</b>						
<b>Main Terai</b>						
- Rs/ha	9 819	-7 256	-2 965	1 348	1 348	1 348
- Rs '000/DTW (48 ha)	471.3	-348.3	-142.3	64.7	64.7	64.7
<b>Inner Terai</b>						
- Rs/ha	5 338	-2 921	871	4 642	4 642	4 642
- Rs '000/DTW (48 ha)	256.2	-140.2	41.8	222.8	222.8	222.8
<b>Improved Performance (future)</b>						
<b>Main Terai</b>						
- Rs/ha	12 550	-9 071	-3 113	2 846	6 408	7 596
- Rs '000/DTW (48 ha)	602.4	-435.4	-149.4	136.6	307.6	364.6
<b>Inner Terai</b>						
- Rs/ha	6 513	-2 596	3 133	8 842	12 279	13 425
- Rs' 000/DTW (48 ha)	312.6	-124.6	150.4	424.4	589.4	644.4

Note: \* (without tubewell net income) x 1.25 for a full year

Source: GDC estimates.

Taking year one as the year when the well is installed repayments under typical present conditions some repayment of capital costs could be made from year four in the main Terai and a year earlier in the Inner Terai when benefits are greater, as demonstrated earlier. In the future, when cultivation practices are improved, the repayment possibilities would be as summarised below:

Improved Case	Year				
	2	3	4	5	6
<b>Main Terai</b>					
Ratio: rainfed income	0.35	0.94	1.53	1.89	2.01
"Surplus" (Rs/ha)	-	-	2 850	6 410	7 600
(Rs/DTW)	-	-	136 600	307 600	364 600
<b>Inner Terai</b>					
Ratio: rainfed income	0.75	1.86	2.95	3.61	3.83
"Surplus" (Rs/ha)	-	3 310	8 840	12 280	13 430
(Rs/DTW)	-	150 400	424 400	589 400	644 400

The relative differences between the two areas are the same but repayments would be significantly higher.

Year	Main Terai (Rs/ha)	Main Terai (Rs/DTW)	Inner Terai (Rs/ha)	Inner Terai (Rs/DTW)

**APPENDIX V MEDIUM AND DEEP TUBEWELL GROSS MARGIN BENEFITS**

## APPENDIX I

### STUDY AREA POPULATION AND FARM STRUCTURE

#### 1 Population

Details of the Study Areas 1971, 1981 and 1991 population by District Development Region and Study Area analysis strata are given in Table I.1. The number of households and household sizes is shown in Table I.2. Table I.3 from 1981 census data gives the District figures for literacy and the proportions of the population that were economically active in agriculture at that time. The figures will have changed but data from the 1991 census are not available.

#### 2 Farm Structure

The following tables of preliminary results from the 1990/91 National Sample Census of Agriculture provide background to the characteristics of agriculture in the Study Area outlined in Chapter 2.

Table I.4      Holding size distribution by District and Study Stratum

Table I.5      Fragmentation of holding by stratum

Table I.6      Land tenure type by stratum

TABLE I.1

## APPENDIX II

### CROP LABOUR REQUIREMENTS

#### 1 Background

Crop labour requirement estimates were derived from a number of sources in Nepal, Pakistan, Indonesia and elsewhere. The requirements, by operation are given in Tables II.1 to II.4.

In each case land preparation by bullock ploughing and puddling has been assumed and all other work is by hand. The tables show the different levels of input related to the crop yields in each stratum adopted for the study analyses. They are given for four yield cases :

Without Tubewell Present (rainfed)

Without Tubewell Future (rainfed)

With Tubewell Present - Base Case

With Tubewell Future - Improved Performance Case

## APPENDIX III

### CROP BUDGETS

#### 1 Financial

The crop gross margin budgets used in the analyses are set out at 1993 financial prices in Tables III.1 to III.8 for each of the four Study Strata: West, Central, East and Inner Terai. The basis for the gross margins is discussed in Chapter 4 and, in detail in Volume 2, Part B, Agriculture.

#### 2 Economic

Tables III.9 to III.16 present the same budgets at projected economic values which are at constant 1993 prices. The derivation of the values is given in Chapter 3.

## APPENDIX IV

### SHALLOW TUBEWELL BENEFITS

#### 1 Shallow Tubewell Benefits

Tables IV.1 to IV.8 set out details of the STW gross margins for the four Study Strata and at financial (IV.1-IV.4) and economic (IV.5-IV.8) prices using the cropping patterns and intensities discussed in Chapter 5 and the individual crop budgets presented in Chapter 4.4 and Appendix III.

Each table sets out the benefits for the following STW cases :

- (i) Base or present achievement levels
- (ii) Improved Performance which is equivalent to possible future production levels
- (iii) High Utilisation assuming Base Case production
- (iv) High Utilisation combined with Improved Performance output.

The tables also set out the present and forecast future crop production values under rainfed conditions. These are used to calculate the following incremental, or increased benefits from STWs in each stratum.

#### Present

Base STW Utilisation

High Utilisation

#### Future

Improved Performance

High Utilisation and Improved Performance

## APPENDIX V

### MEDIUM AND DEEP TUBEWELL GROSS MARGIN BENEFITS

#### 1 Financial Benefits

Tables V.1 to V.8 set out the calculation of incremental crop gross margins each hectare for the cropping patterns adopted for medium and deep tubewells. The tables illustrated the derivation of the unit area figures from a 90 s DTW with a 90 ha command area. The figures for other sizes of tubewell are very similar since they have the same cropping patterns.

The tables cover three land classes in the Main Terai using Central Stratum price data and one land class in the Inner Terai using price appropriate to that stratum.

Main Terai	Financial	Economic
Land Class 2 mixed	E.1	E.5
Class 2 upland	E.2	E.6
Class 2R Lowland	E.3	E.7
<b>Inner Terai</b>		
Land Class 2 (mixed)	E.4	E.8

The assumptions behind the derivation of benefits are given in Chapter 6 and earlier sections.

Each table also shows the present and future incremental TW gross margins.

As discussed in Chapters 6 and 8 this is used to illustrate the comparative benefits to the different types of TW; two DTW and three MTW of different capacities; expected in each of the three land classes; and the difference between tubewells in the Main and Inner Terai strata on Land Class 2 (mixed).

The gross margins do not include the cost of pumping water or of course fixed costs such as land tax and the repayment of capital costs. These are included in Chapter 7, Tubewell Costs.
